Prostate cancer becomes most common cancer diagnosis in England

There were 55,033 diagnoses of prostate cancer in England in 2023 compared with 47,526 diagnoses of breast cancer

‘Better and cheaper’: the case for prostate cancer screening among black men

Decision over routine PSA testing is due at end of this month, though some feel the supporting data is unclear

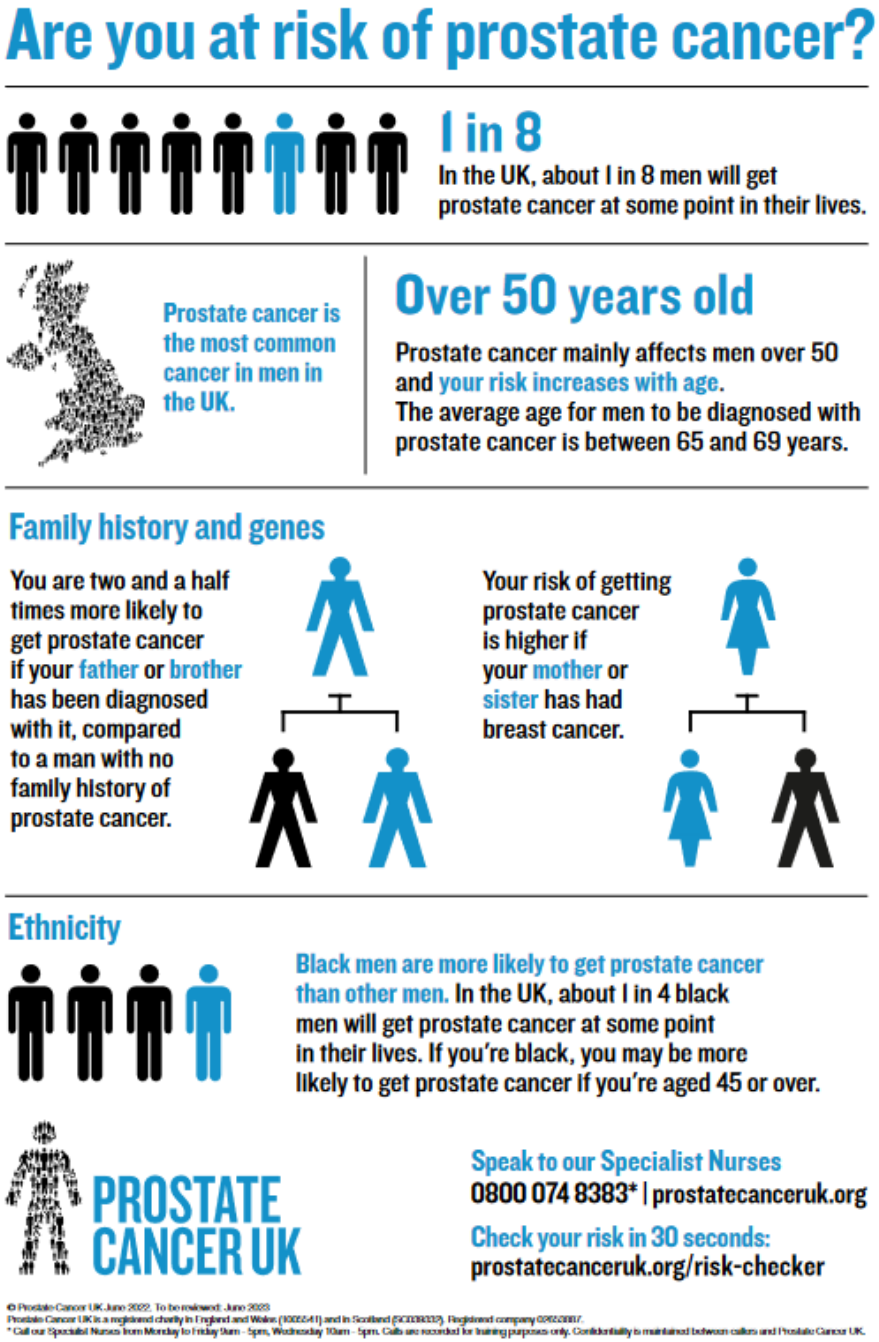
Prostate Cancer

- Most commonly diagnosed cancer in UK men
  - 55,485 UK men diagnosed in 2022
  - 1 in 8 UK men diagnosed in lifetime
  - 1 in 4 UK Black men diagnosed in lifetime
- Second commonest cause of cancer death
  - 13,237 UK deaths in 2022



1. European Cancer Information System (ECIS) Data Explorer accessed 14/5/2024 at https://ecis.jrc.ec.europa.eu/index.php

Diagnosis & staging

2024 in England

58,218

men were **diagnosed** with prostate cancer

9%

increase compared with 53,462 men in 2023

2023 in Wales

2,402

men were **diagnosed** with prostate cancer

6%

decrease compared with 2,551 men in 2022

Disease presentation

For men diagnosed between January - December 2022 in England and between April - December 2023 in Wales*

12% E 20% W

of men presented with **metastatic** disease in England (E) and Wales (W)

5-19%

17-22%

5,696 2022
men were diagnosed with metastatic disease in England

8%

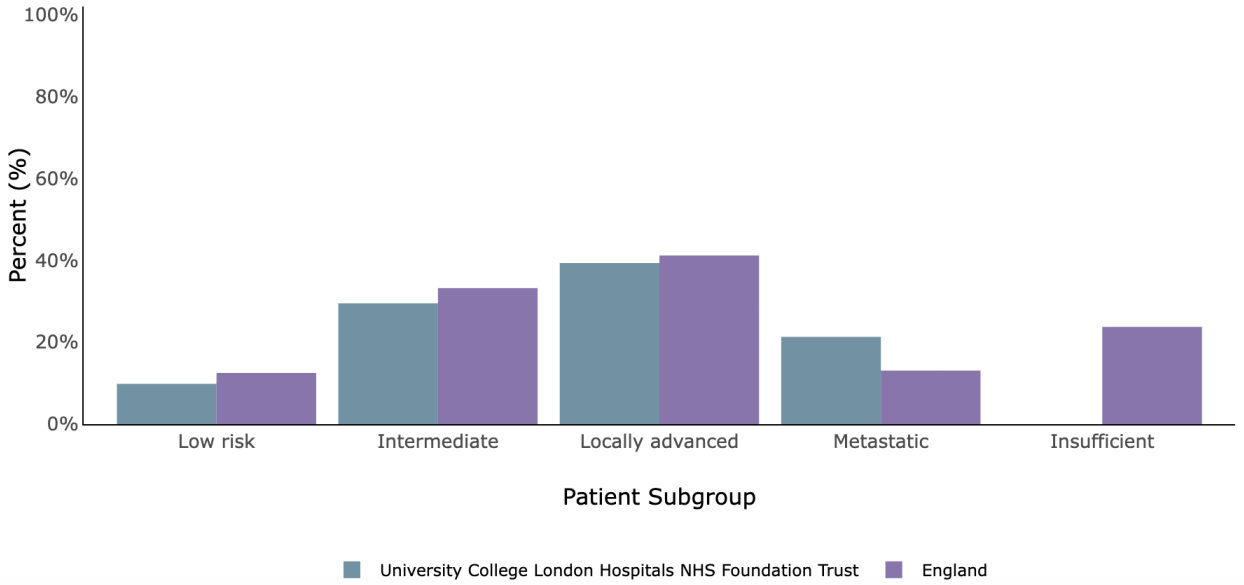
decrease compared with **6,161** 2021

NPCA
National Prostate Cancer Audit

National Prostate Cancer Audit - State of the Nation Report (01 Jan 2022 - 31 Dec 2022)

Prostate cancer risk group

Note, the time periods differ between England and Wales. England is patients diagnosed 1st Jan - 31st Dec 2022 and Wales is patients diagnosed 1st April - 31st December 2023.



NPCA
National Prostate Cancer Audit

Treatment allocation

For men diagnosed between January - December 2022 in England and between April - December 2023 in Wales

Low-risk*, localised disease

7% E — 2-40%

7% W — 3-10%

High-risk/locally advanced disease

69% E — 46-87%

68% W — 48-87%

of men had **radical treatments** in England (E) and Wales (W)

Low-risk: T stage 1/2, Gleason ≤6, M/N 0 or missing = CPG 1 (Cambridge Prognostic Group 1)

Should we screen for prostate cancer?

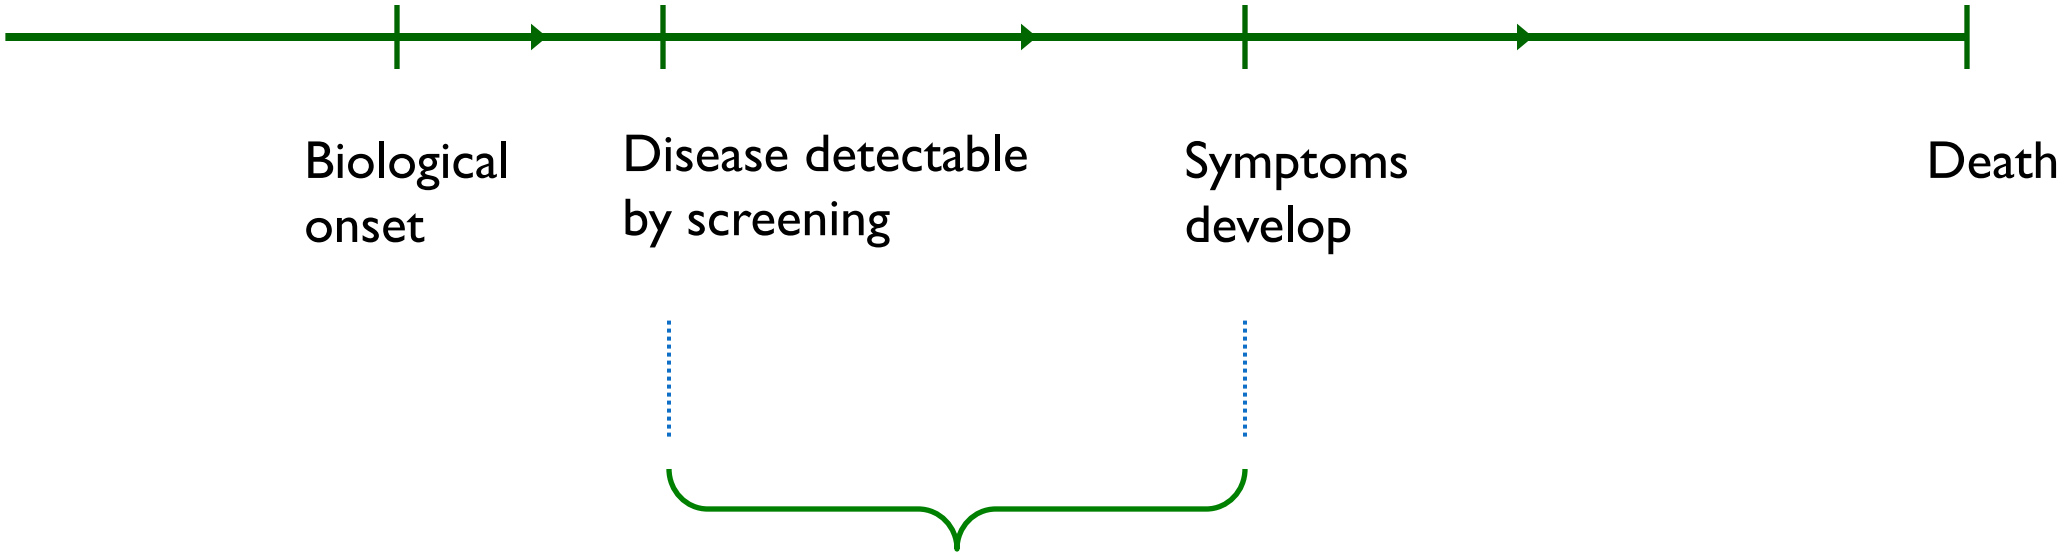
Screening

- *“identifying apparently healthy people who may have an increased chance of a disease or condition….Individuals can then be offered more information, further tests or treatment as appropriate.” UK National Screening Committee”*

- Proactive approach by a screening provider (NHS) to people who are largely asymptomatic and not yet diagnosed with prostate cancer
- Does NOT rely on people approaching their GPs

PROSTATE CANCER UK
TRANSFORM

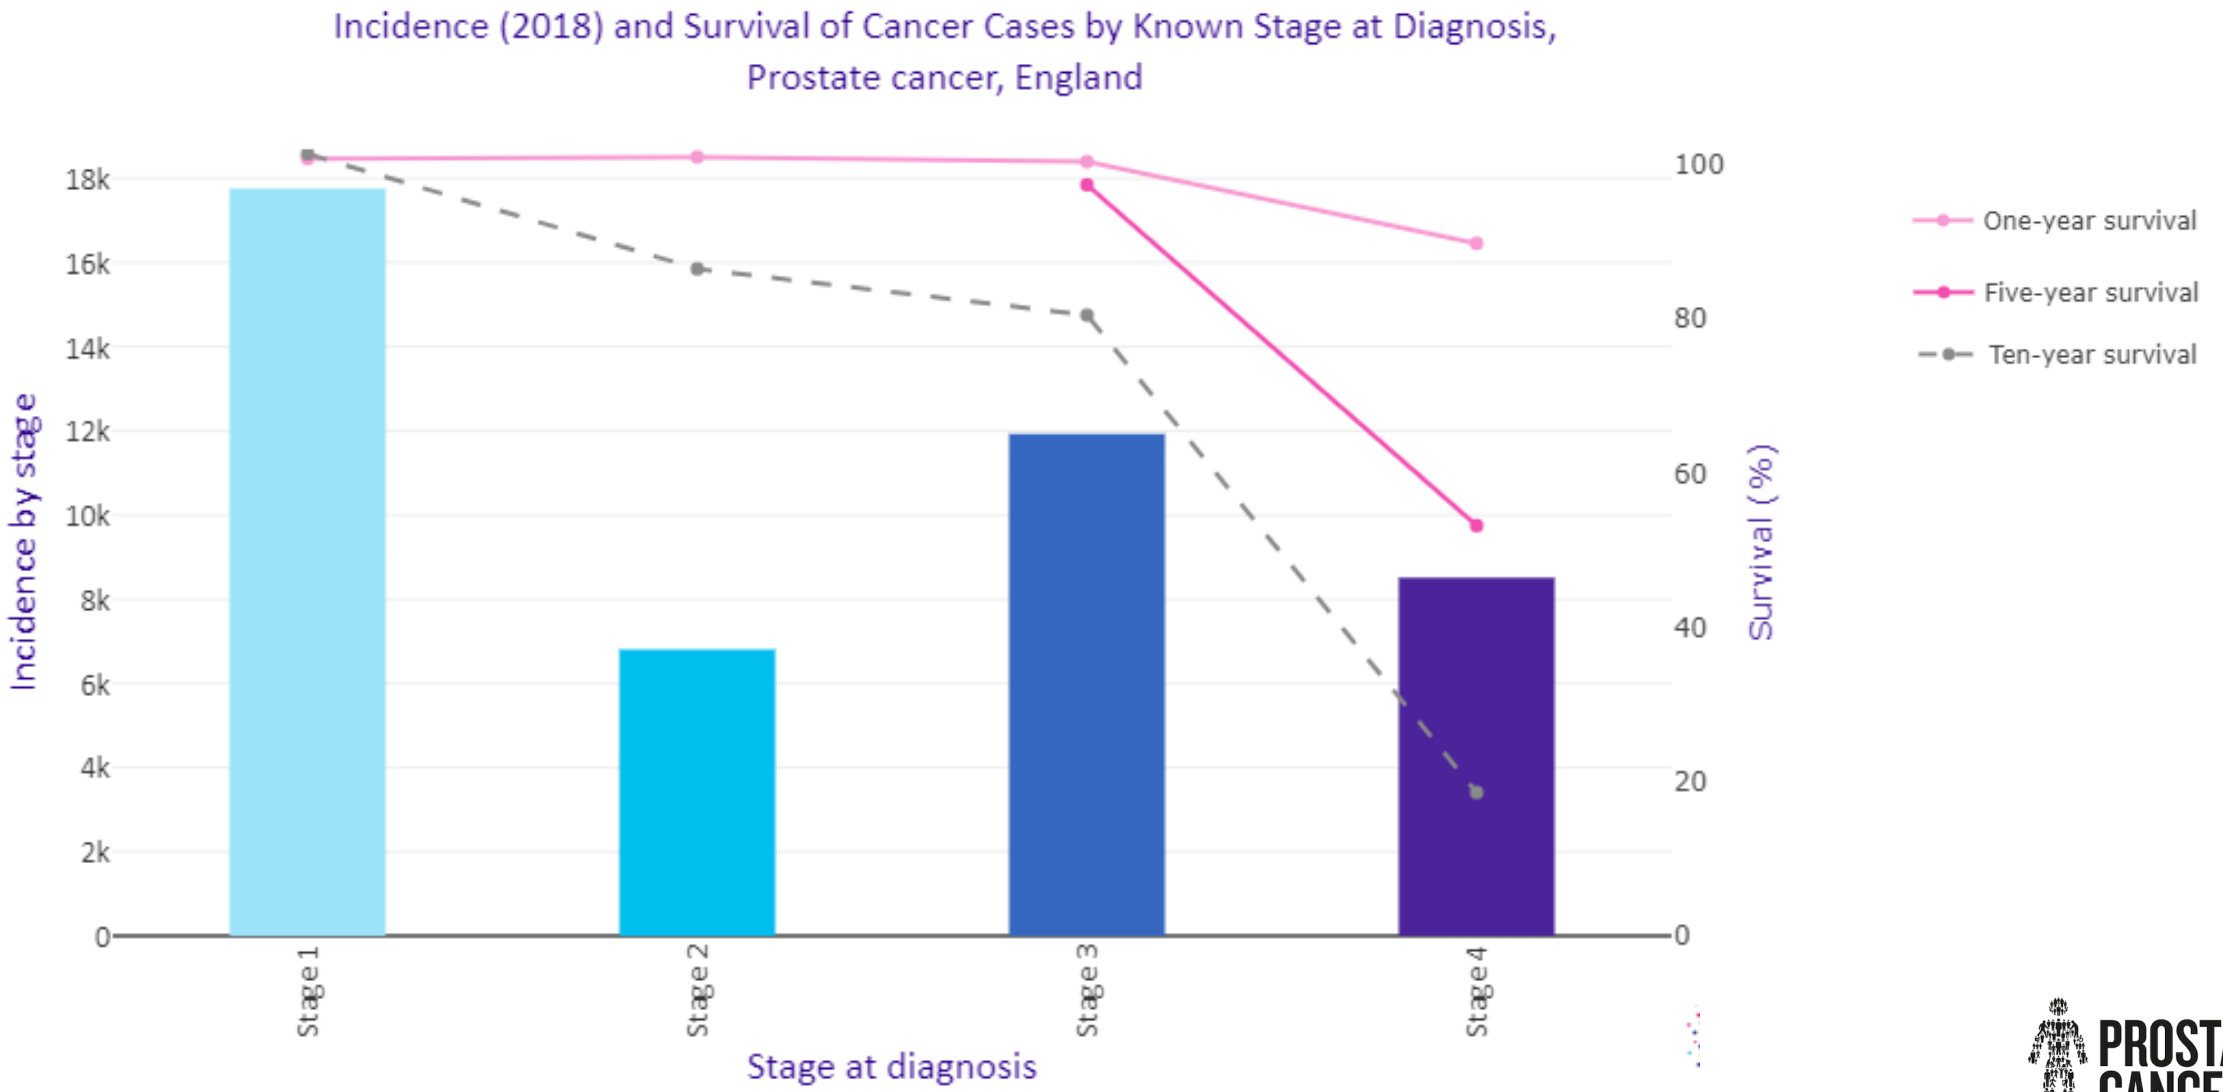
How screening works



PROSTATE CANCER UK
TRANSFORM

With thanks to Professor Rhian Ghabe, QMUL

Earlier Stage, Better Survival



Screening or early detection could save lives

PROSTATE CANCER UK
TRANSFORM

Is there a benefit of earlier diagnosis?

Example: 3 scenarios for the same person

	Measured survival from diagnosis	True increase in survival ?
1	10 years	
2	15 years	✗,0 years (because of 5 years lead time)
3	20 years	✔ , 5 years

With thanks to Professor Rhian Ghabe, QMUL

PROSTATE CANCER UK
TRANSFORM

Potential harms of screening

- Does it save lives?
  - Lead time bias – know they have cancer for longer
  - Length bias – screening picks up slow growing, better prognosis cancers
  - Selection bias – healthy volunteers might be at lower risk of prostate cancer death due to other healthy behaviours
- Potential harms
  - Anxiety
  - Unnecessary invasive biopsies
  - Overdiagnosis
  - Overtreatment
- Costs
- Logistics

ERSPC
European Randomized Study of Screening for Prostate Cancer

- ERSPC 23 year data on 162 389 men (55–69 yrs) from 1993 to 2020 or 23 years
- PSA testing with Hybritech assay systems (Beckman Coulter)
- Most centres used a cut off of 3ng/ml but
  - Italy used 4 ng/ml with DRE and TRUS for PSA 3-39.9 ng/ml
  - Finland added DRE for PSA 3 - 3.9 ng/ml until 1998 then F:T $\leq$ 0.16 after that
- 4 year interval in most but
  - Sweden & France 2 year interval
  - Belgium 7 year interval
- Average 2 screening visits per person

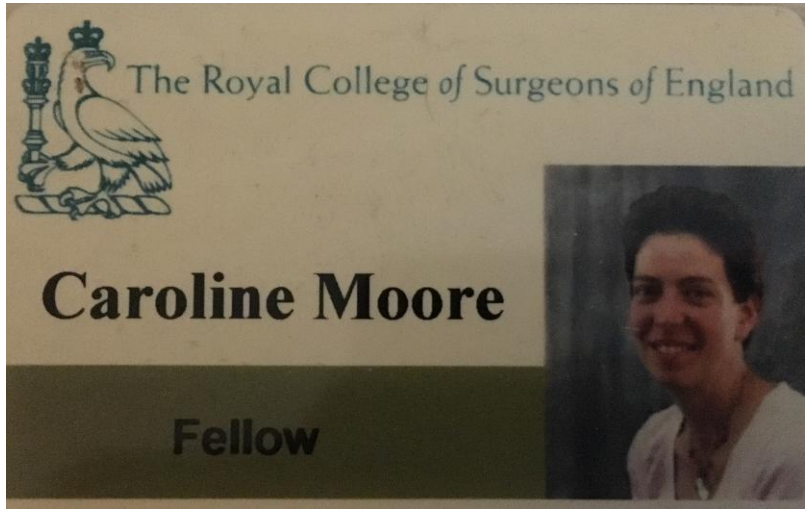
Things change over time….

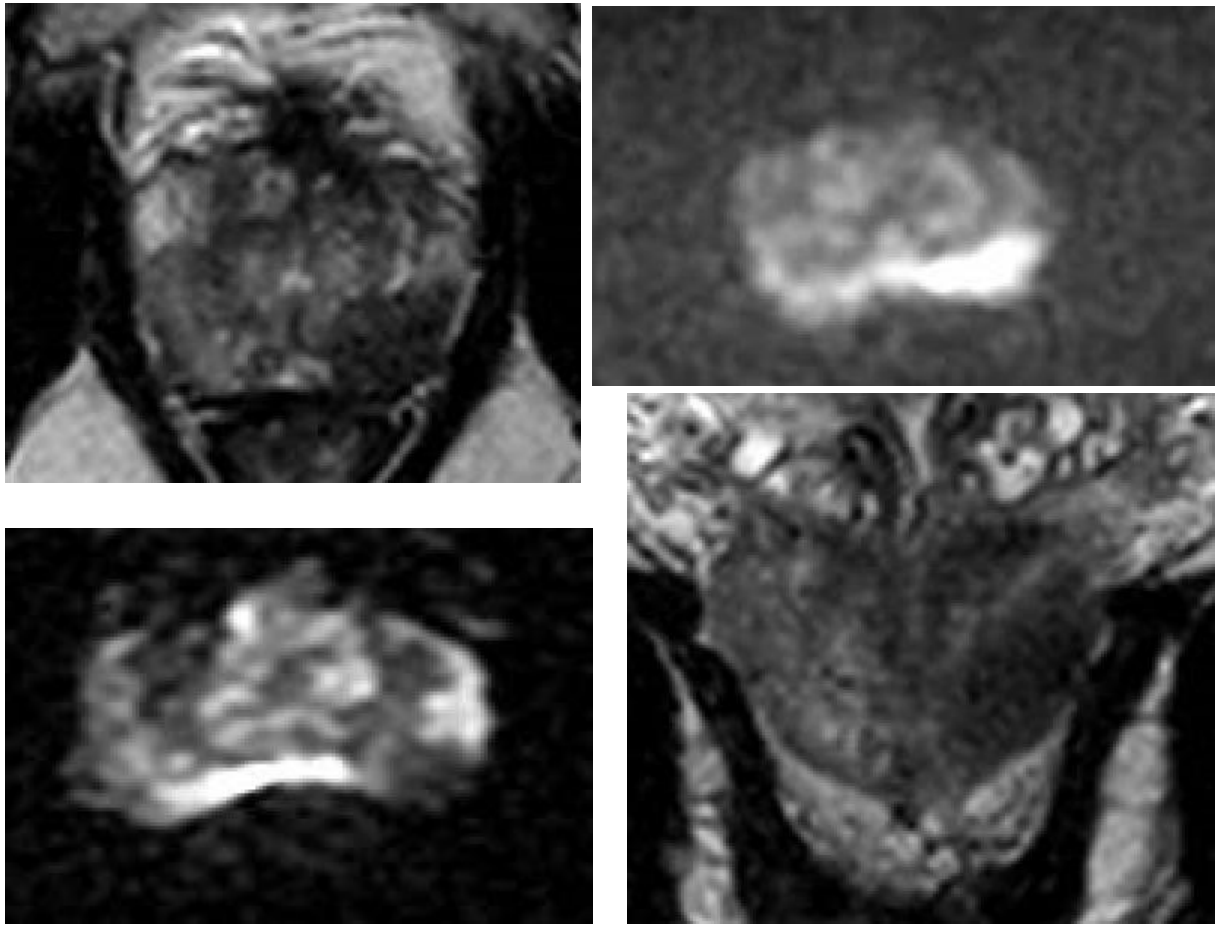


October 2002

Now!

@mrsprostate

MRI can selectively detect significant cancer



We become what we behold. We shape our tools and then our tools shape us.

— Marshall McLuhan —

What we want from modern screening

Maximise benefit

- Reduce prostate cancer deaths by finding the most harmful cancers
- Use the best tests available
- Optimise prostate cancer treatment

Minimise harm

- Reduce overdiagnosis
  - Reduce anxiety
  - Reduce unnecessary re-testing
- Reduce over treatment

PROSTATE CANCER UK

Next steps in screening in the UK

UK National Screening Committee

UK NSC requires robust evaluation to recommend that the UK government invests in national prostate cancer screening programme….. this means:

- **Randomised controlled trial across the UK**
- **Making sure diverse population offered screening**
- **Making sure Black men who are at higher risk are represented**
- **Adequate proportion of those invited taking up the offer of screening**
- **Evaluating which is the best screening test**

TRANSFORM Aims

- Robust UK trial of modern screening approaches
- Assess acceptability, clinical & cost-effectiveness of different strategies
- Assess barriers and facilitators to equitable engagement across the population
- Create a data, imaging, histological and biological repository

PROSTATE CANCER UK
TRANSFORM

TRANSFORM: 3 stage design

Stage 1 (3 years)

- Pilot 4 screening interventions
- Evaluate how to deliver pivotal trial assessing key processes and assumptions
- Short-term outcomes
- Develop bio-digital twin protocols

16,500 men

2

Stage 2 (6 years)

- Main trial of optimal intervention
- Medium-term clinical outcomes
- PROMS: quality of life.
- Costs and resources
- Create bio-digital twin

TRANSFROM Discovery

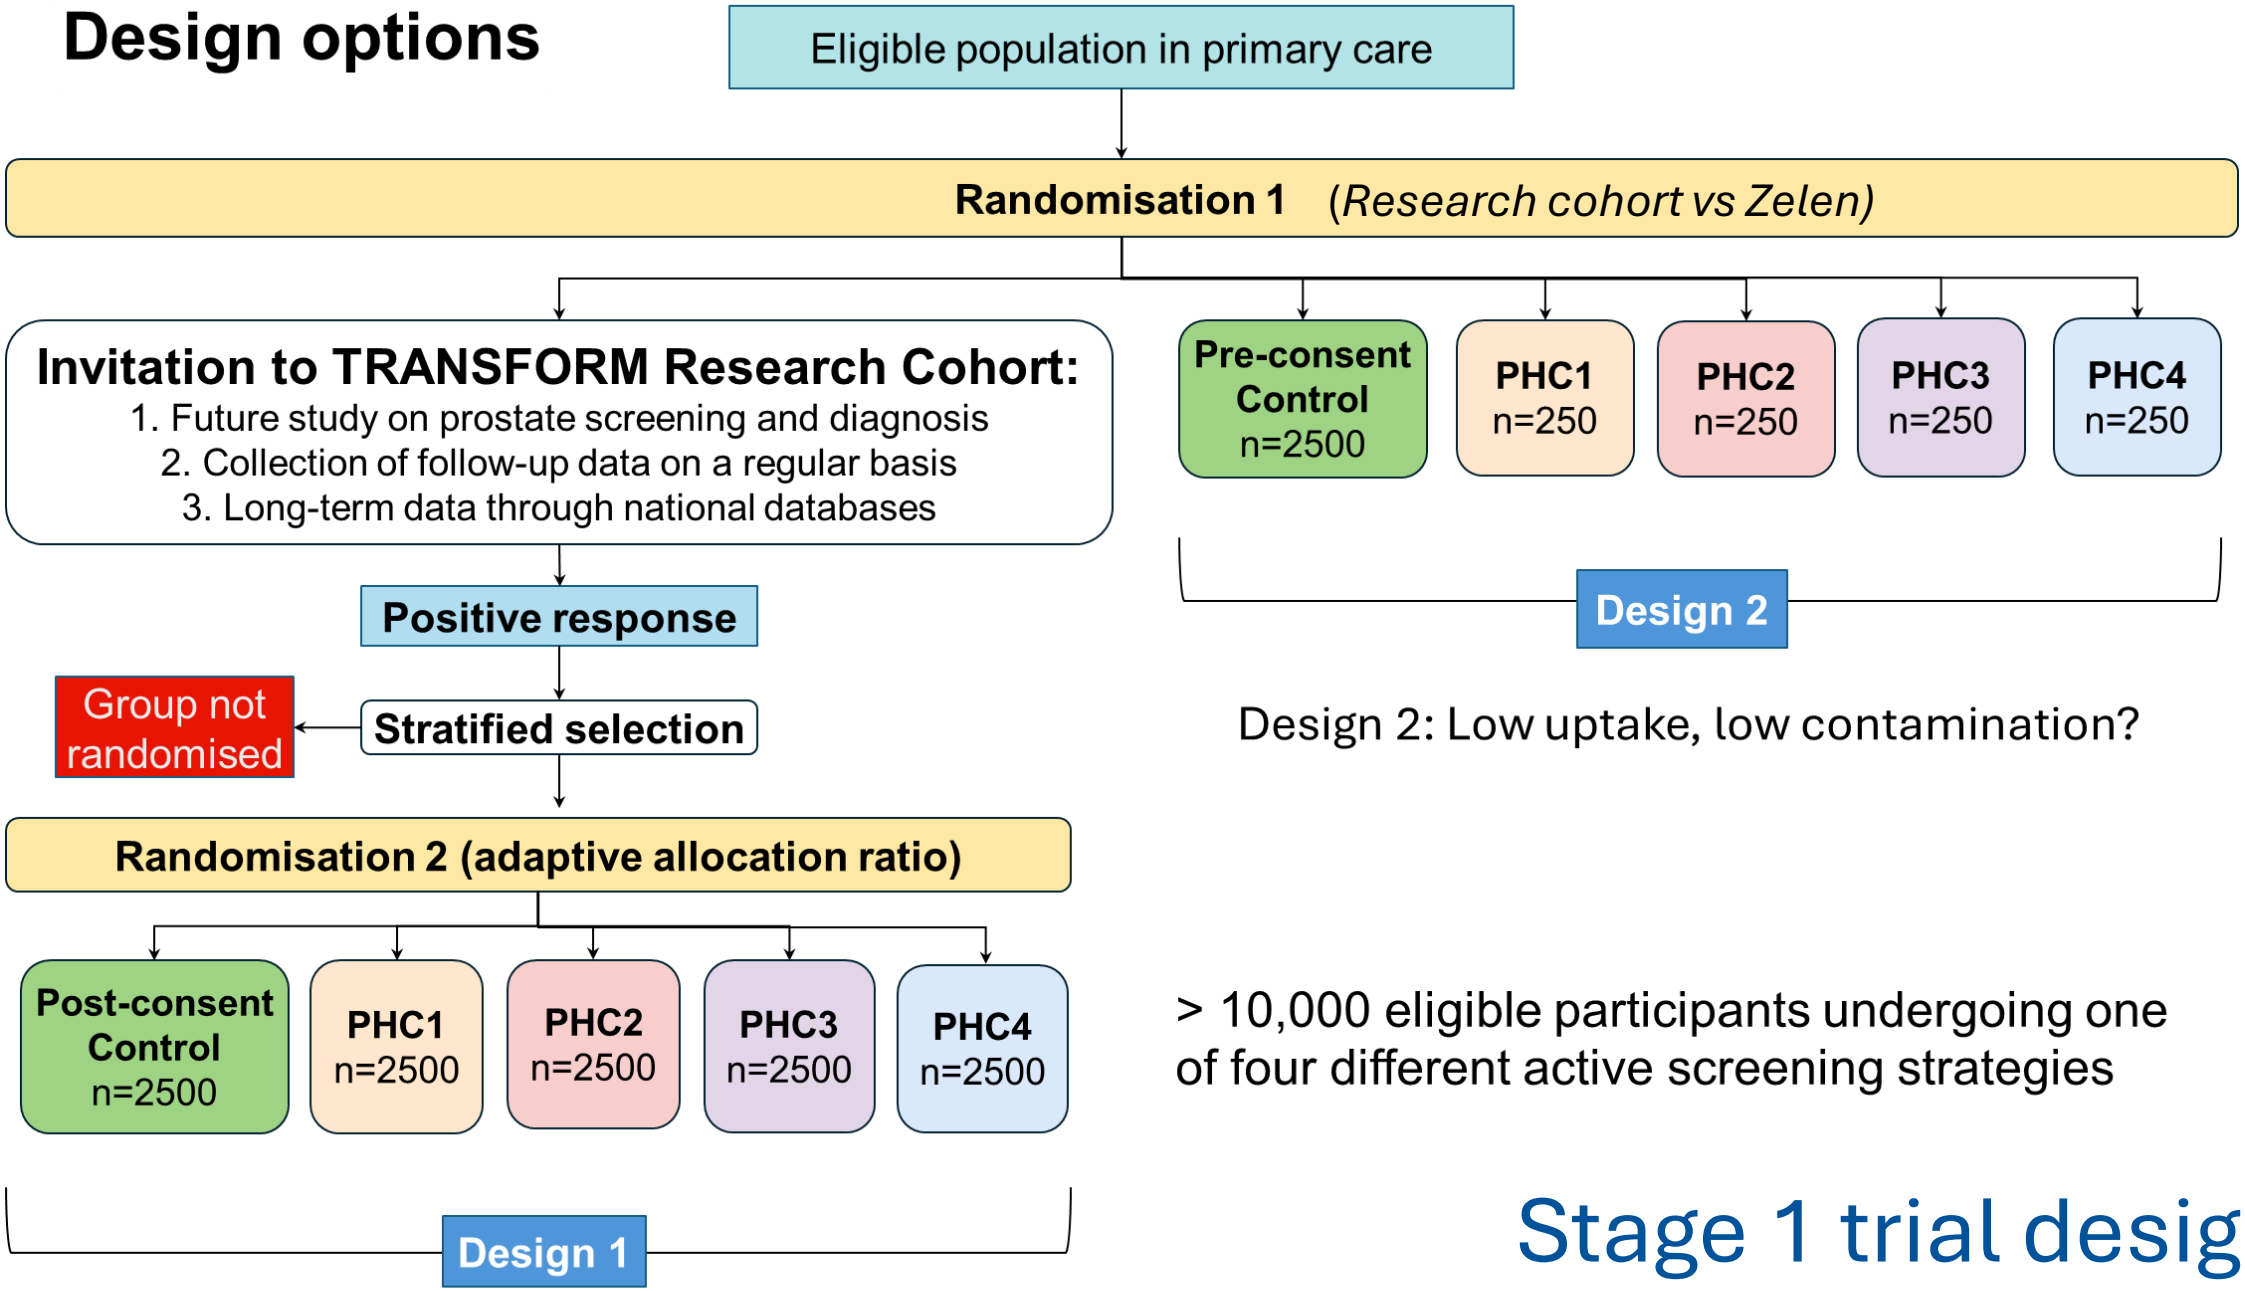
180,000– 500,000 men

3

Stage 3 (10 years)

- Evaluate long-term primary outcomes through linkage to national databases

Design options



Design 2: Low uptake, low contamination?

Design 1: High uptake, high contamination?

Active surveillance for prostate cancer

TRADITIONAL ACTIVE SURVEILLANCE

- Single protocol for follow up across a spectrum of risk of progression
- PSA and digital rectal examination done regularly
- Uptake of surveillance varies internationally & locally
  - 95% suitable men in UK
  - 60% suitable men US
- Protocols suggest regular biopsies but they are not always done
  - USA data – 40% biopsy compliance at 2 years, <20% compliance after that
  - PRIAS data – highest compliance 60% at year 4, sometimes <10%
- 1 in 4 men with no clinical change choose radical treatment as they don’t like surveillance
- Men on active surveillance are 10 x as likely to die from heart disease than prostate cancer
- Must consider co-morbidities in men on active surveillance

Best practice recommendations

- DRE can be omitted when MRI issued
- Consider omitting routine biopsy when PSA, MRI are stable
- Change in PSA should lead to MRI not biopsy or treatment
- Any change to active treatment should be based on a combination of a change in clinical factors and patient discussion
- Men with clinical parameters suitable for AS but may be at risk of psychological harm should be offered psychological support rather than radical treatment

UCLH active surveillance

- Determine risk factors before enrolment on AS
  - PSA & PSA density
  - MRI – visible with Likert 4/5
  - Biopsies – Gleason score (including % pattern 4) and maximum cancer core length
- Repeat MRI and /or biopsy if discordant results
- Assess for changes according to baseline risk
- Use PSA and MRI
- Biopsy during surveillance if
  - Change on MRI suggests a change in risk
  - PSA rising and not explained by growth of the whole prostate on MRI

UCLH baseline data

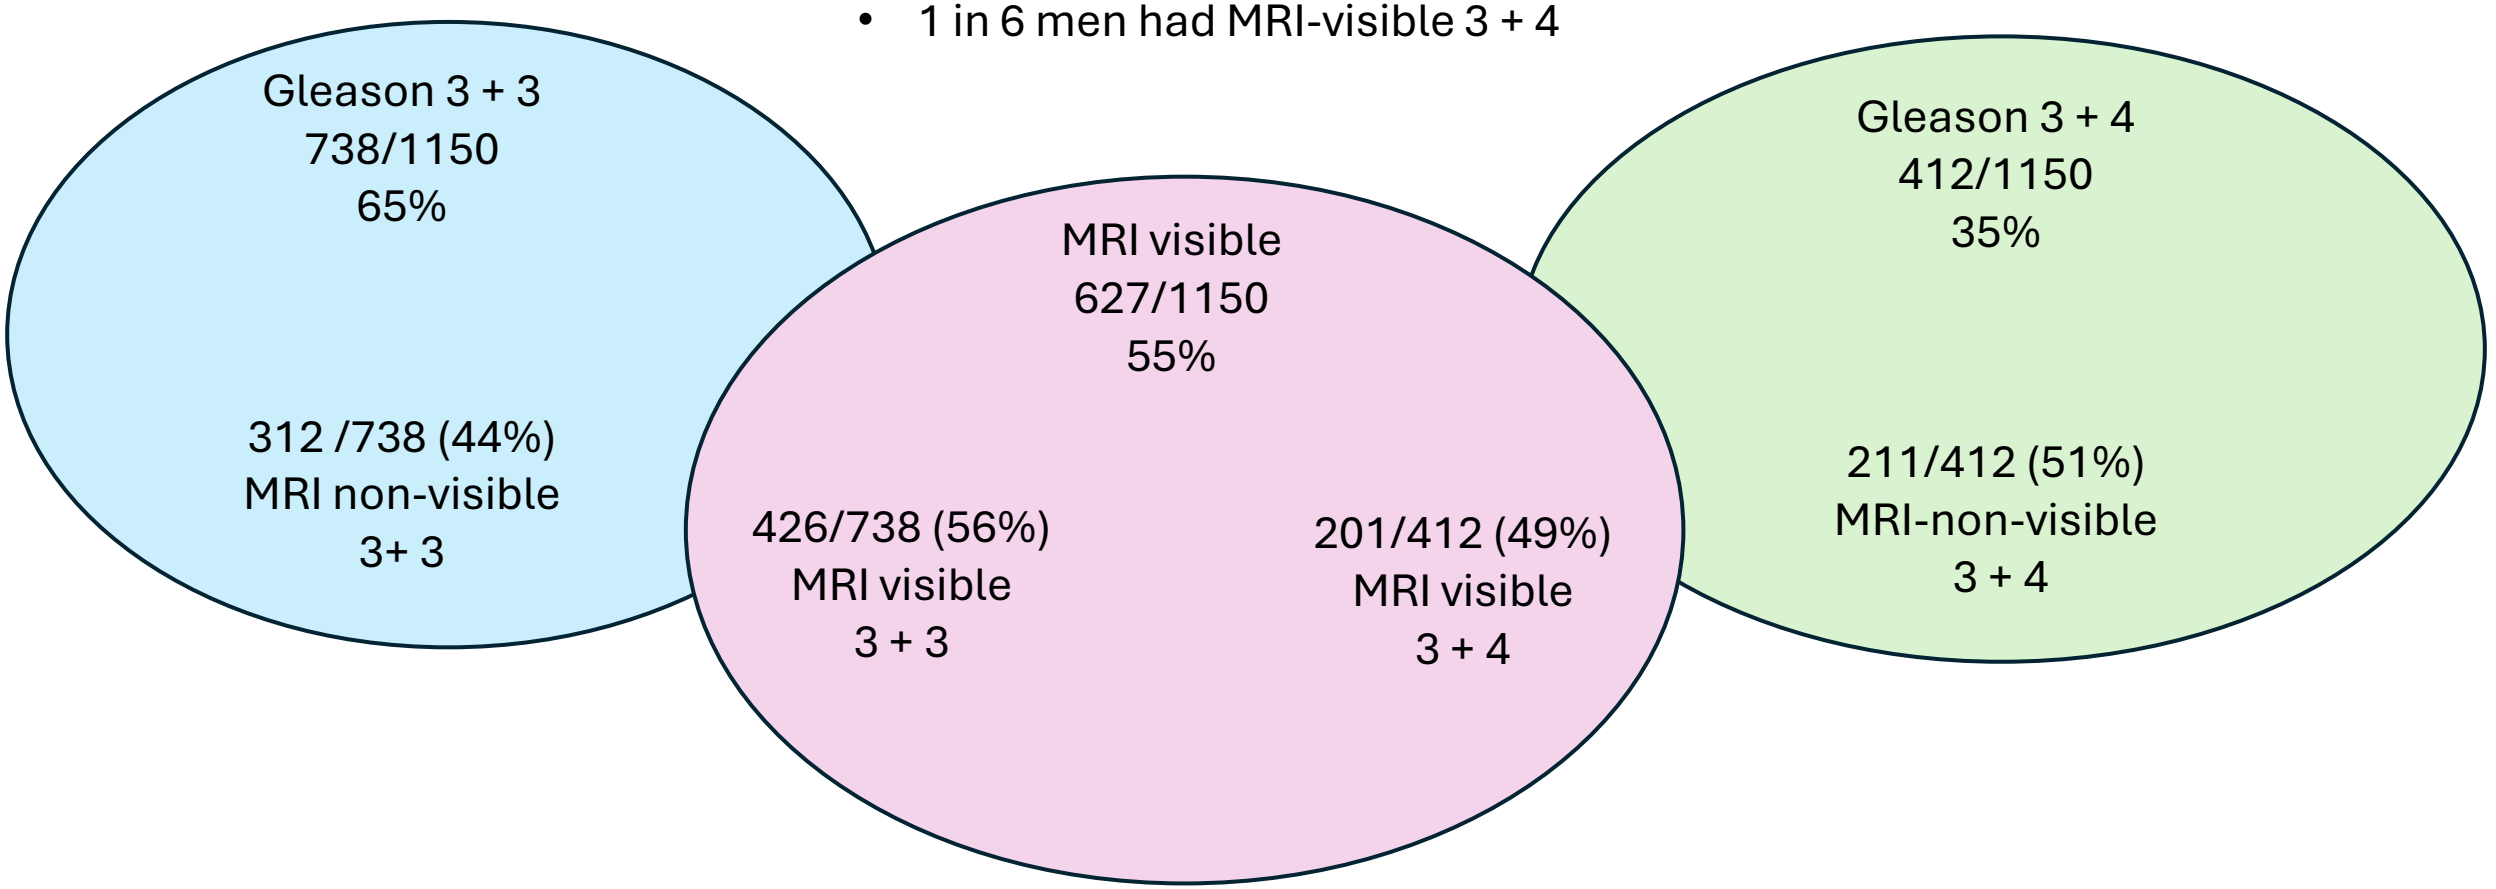
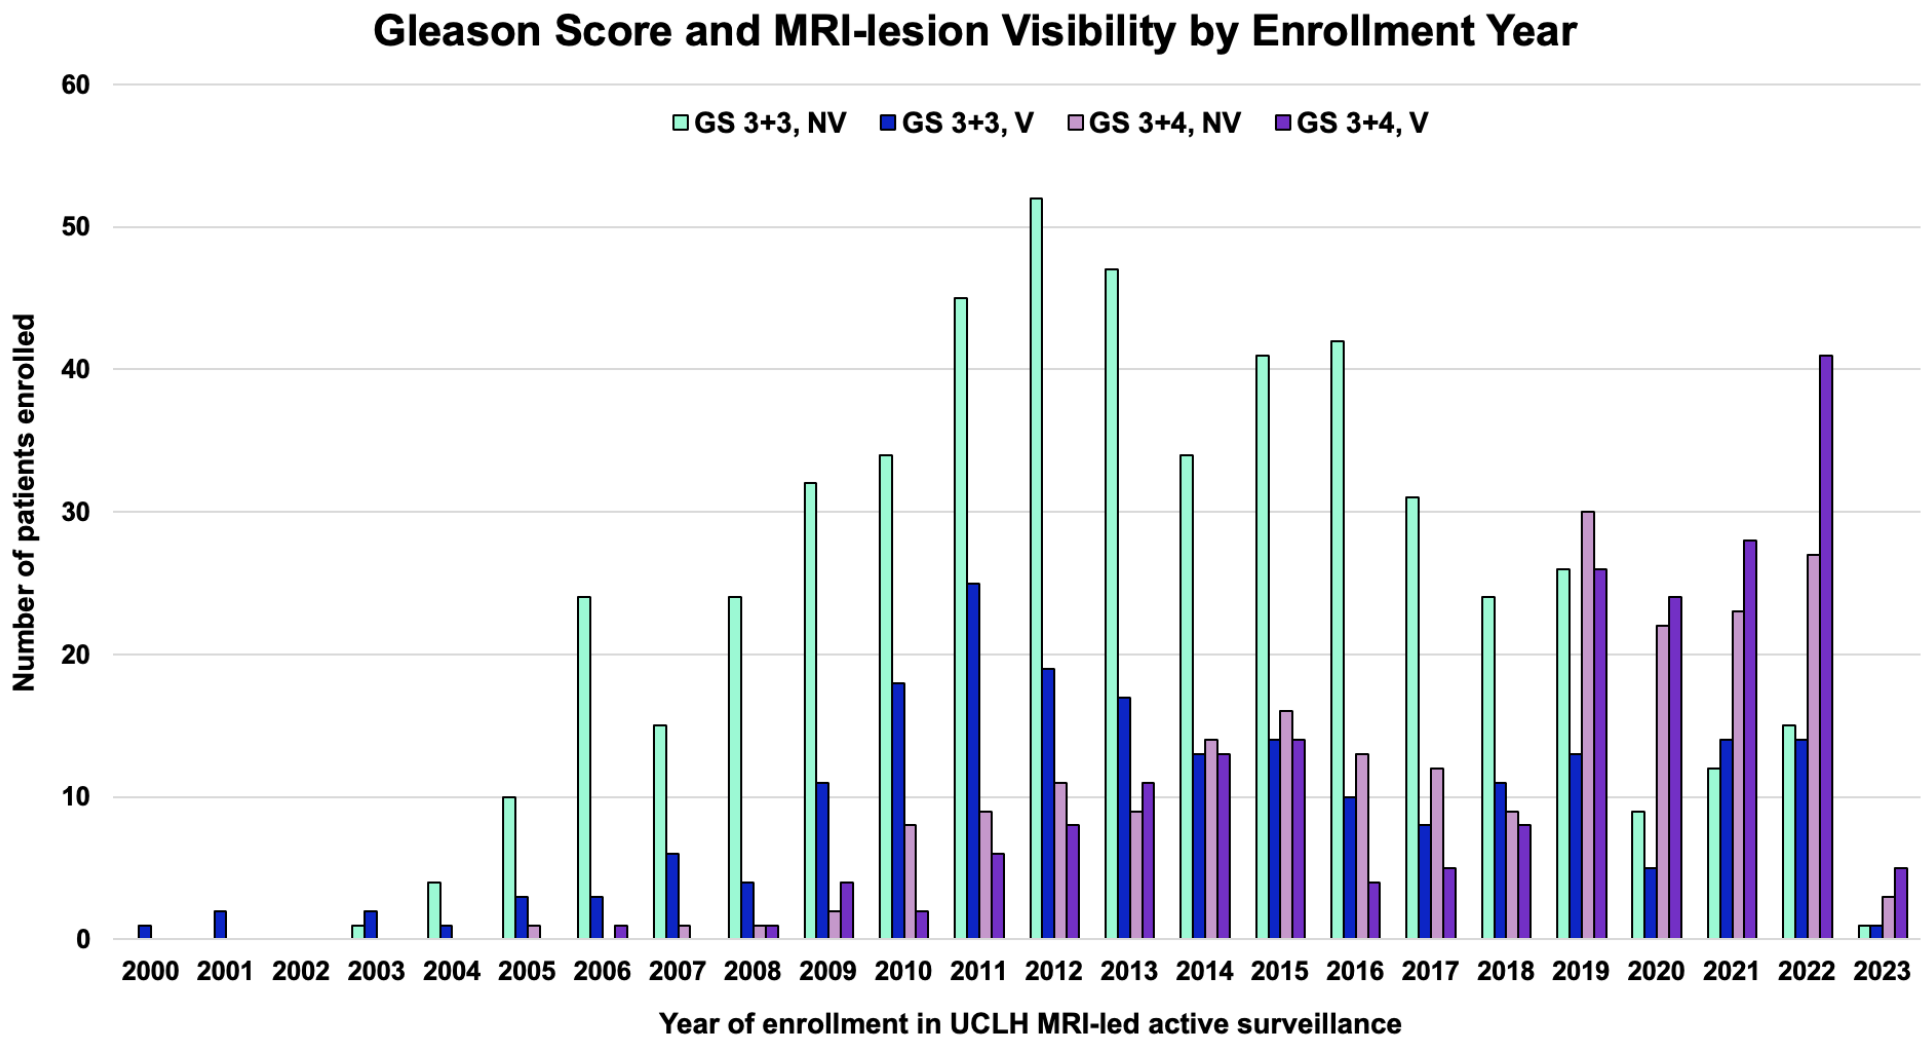
- 1 in 6 men had MRI-visible 3 + 4



Risk by Gleason score & MRI visibility over time



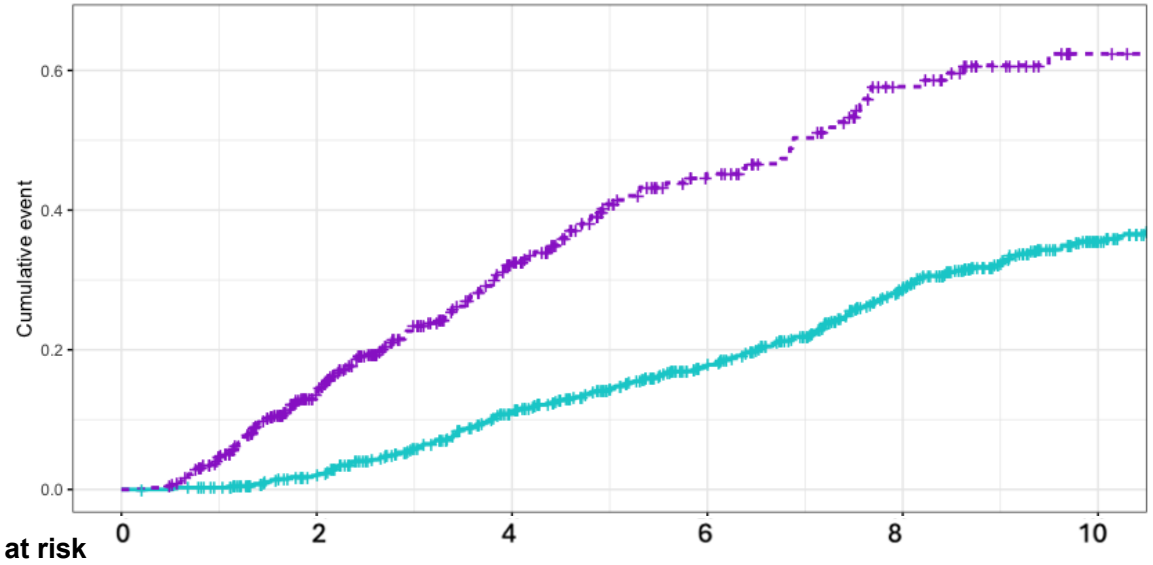
Whole cohort outcomes of MRI-led risk adapted active surveillance

- Event free survival for the cohort
  - 3 years 87%
  - 5 years 76%
  - 10 years 53%
- Biopsy rate – 487/1150 (42%) had a further biopsy on AS
- Histological upgrade to 4 + 3 rare : 67/1150 (6%)
- Only 3% (30 patients) chose treatment despite stable parameters
  - Reduced from 20% in traditional surveillance
- 1 in 3 have had treatment

Can we personalise the outcomes for men considering active surveillance?

Using Gleason score to risk stratify

Active treatment



Number at risk

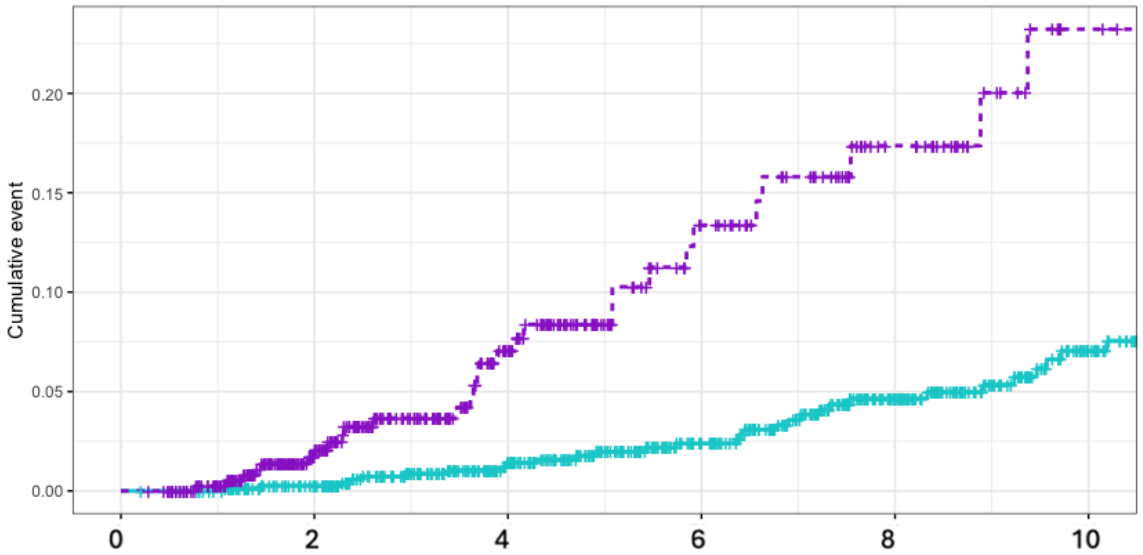
GS 3+3	738	683	563	441	314	197
GS 3+4	412	282	151	82	45	18

GS 3+3 GS 3+4

	5 year treatment rate (%)
Overall cohort	22
3 + 3	14.3
3 + 4	41.9

With particular thanks to Dr Cameron Englman

Histological progression to Gleason ≥ 4 + 3



Number at risk

GS 3+3	738	683	561	440	312	196
GS 3+4	412	280	148	80	45	18

GS 3+3 GS 3+4

	5 year detection of Gleason ≥ 4 + 3 (%)
Overall cohort	3.7
3 + 3	2.0
3 + 4	8.4

With particular thanks to Dr Cameron Englman

Adding MRI-visibility to Gleason score to risk stratify

Active treatment

	5 year active treatment(%)
Overall cohort	22
Non-visible 3 + 3	9
MRI-visible 3 + 3	28
Non-visible 3 + 4	30
MRI-visible 3 + 4	55

With particular thanks to Dr Cameron Englman

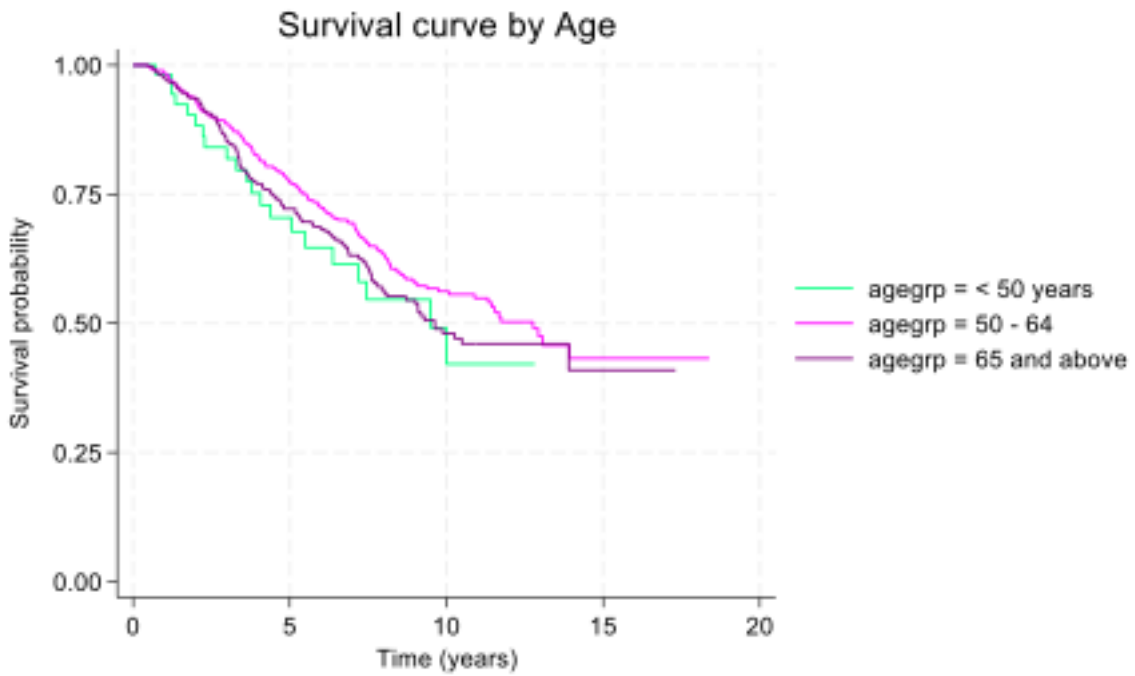
Histological progression to Gleason ≥ 4 + 3

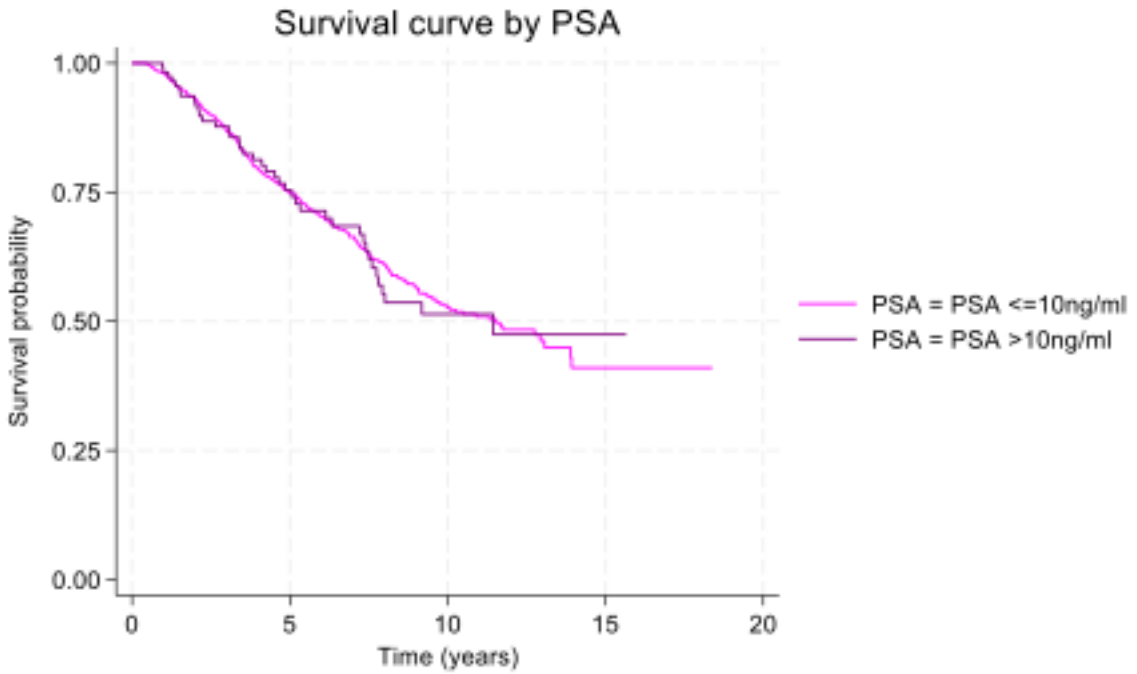
	5 year histological progression to Gleason ≥ 4 + 3 (%)
Overall cohort	3.7
Non-visible 3 + 3	1.2
MRI-visible 3 + 3	4.3
Non-visible 3 + 4	2.5
MRI-visible 3 + 4	17.4

With particular thanks to Dr Cameron Englman

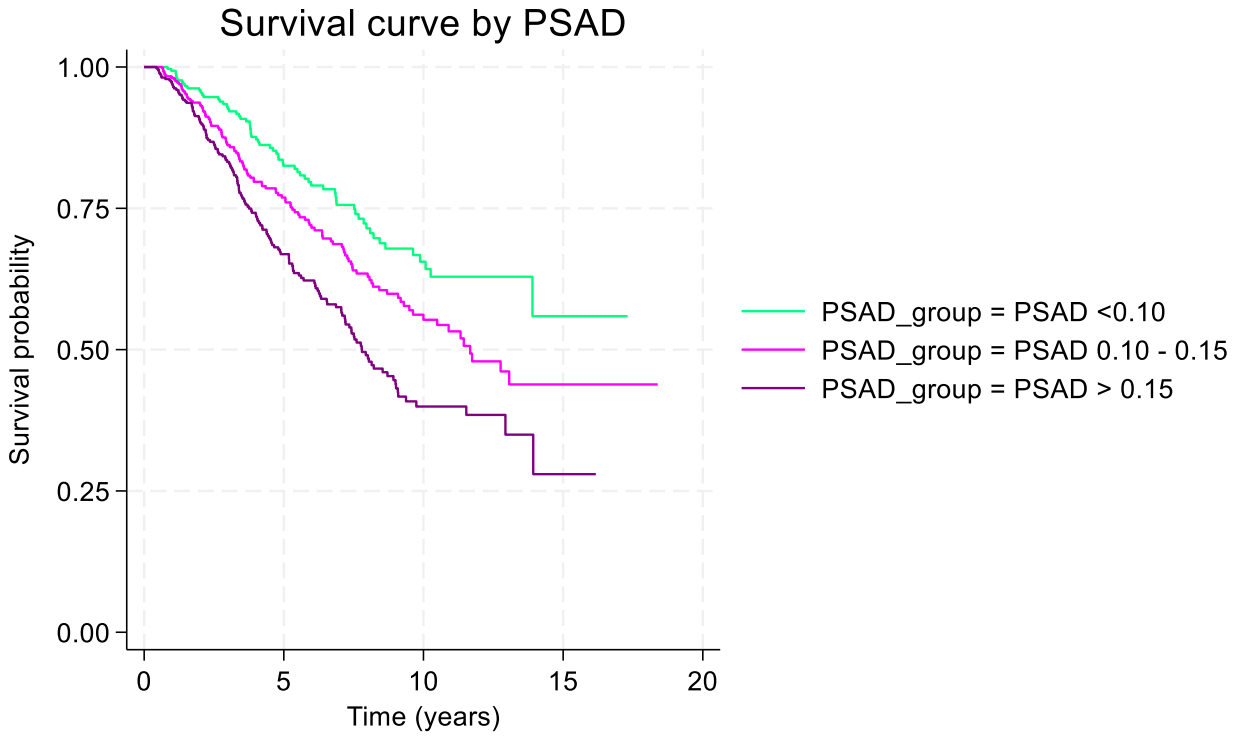
Could we personalize active surveillance by further risk stratification?

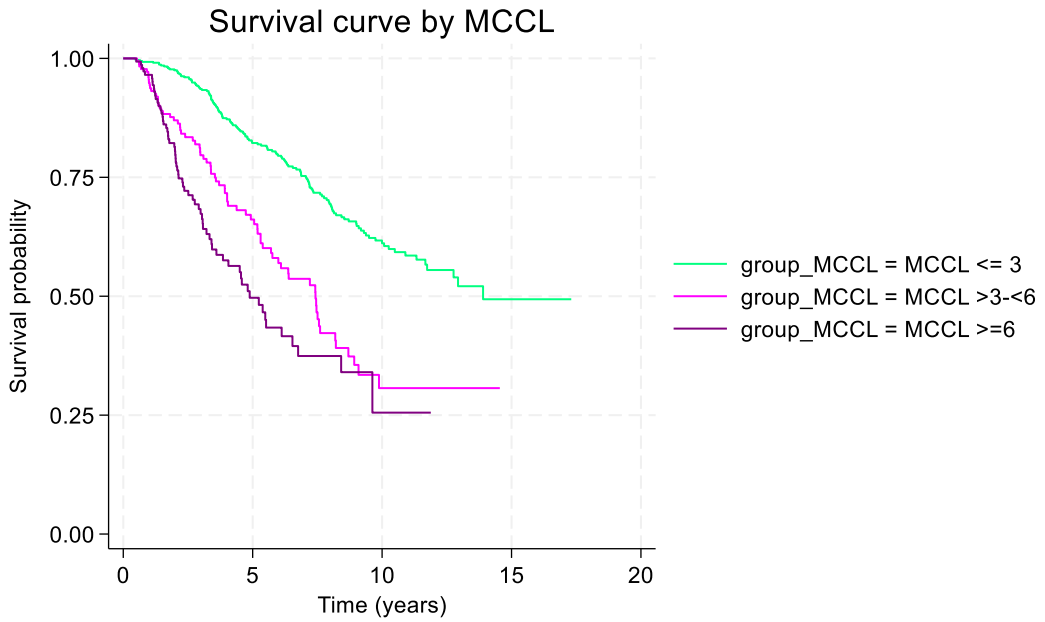
Do age or PSA predict the likelihood of treatment in an MRI-led cohort?





Adding in PSA density and maximum cancer core length





With particular thanks to Dr Busola Adebusoye

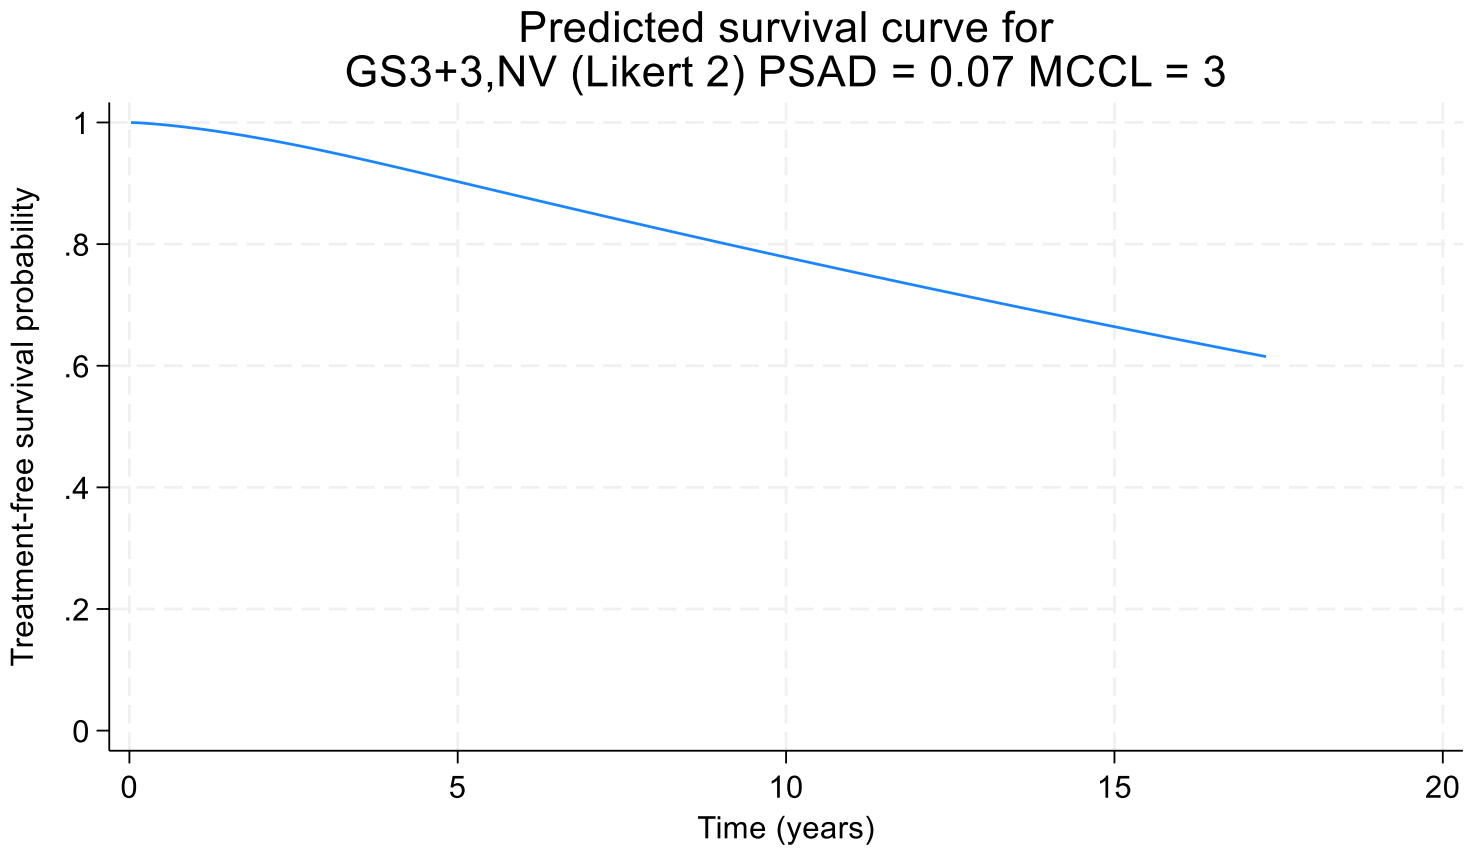
Multi-variable analysis of risk factors in active surveillance

Risk factor	Cox model
	Hazard ratio (confidence interval)
Gleason grade & MRI visibility	
GS 3+3 NV	Ref
GS 3+3 V	2.30(1.65 -3.20)
GS 3+4 NV	2.17(1.53 – 3.09)
GS 3+4 V	4.04(2.84-5.74)
PSA density	
PSAD (<0.10)	Ref
PSAD (0.10-0.15)	1.35(0.97 -1.89)
PSAD (PSAD >0.15)	1.76(1.27-2.43)
Maximum cancer core length	
MCCL < 4	Ref
MCCL 4-<7	1.61(1.22-2.14)
MCCL 7 -<10	1.97(1.29-3.00)
MCCL > 10	2.73(1.50-4.94)

Development of a model to predict treatment free survival

With particular thanks to Dr Busola Adebusoye

Mr Lenny Low Risk
3mm Gleason 3 + 3
Not MR visible (Likert 2)
PSA 4, 60 ml prostate PSA density 0.07

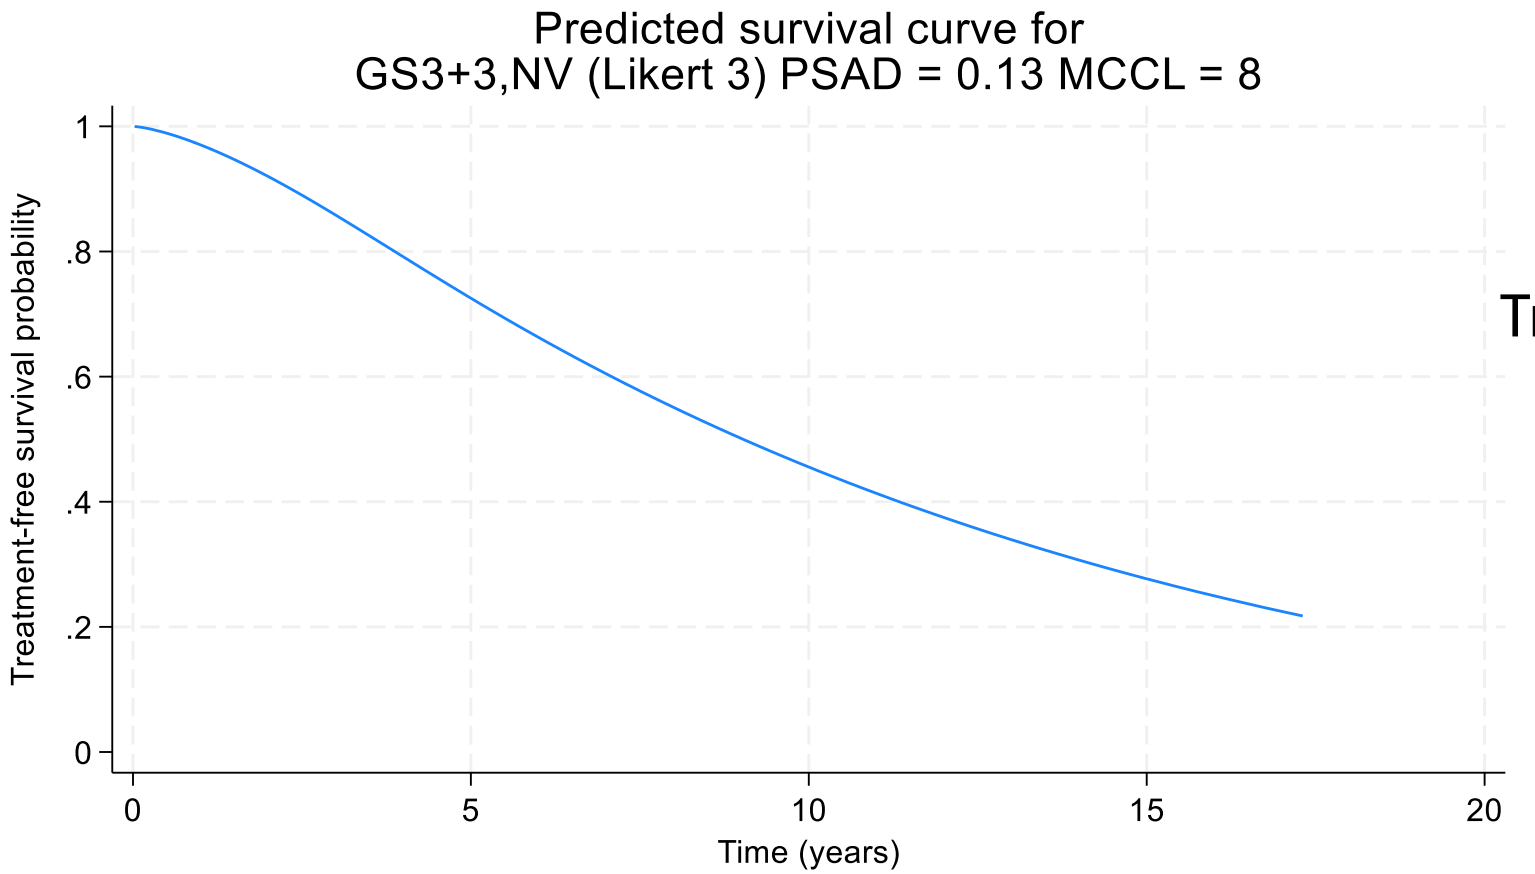


Treatment free survival

- 3 years 95%
- **5 years 90%**
- 10 years 80%

With particular thanks to Dr Busola Adebusoye

Mr Alan also Low risk
8mm 3 + 3
Not MRI visible (Likert 3)
PSA 10.4, 80 ml prostate PSAD 0.13

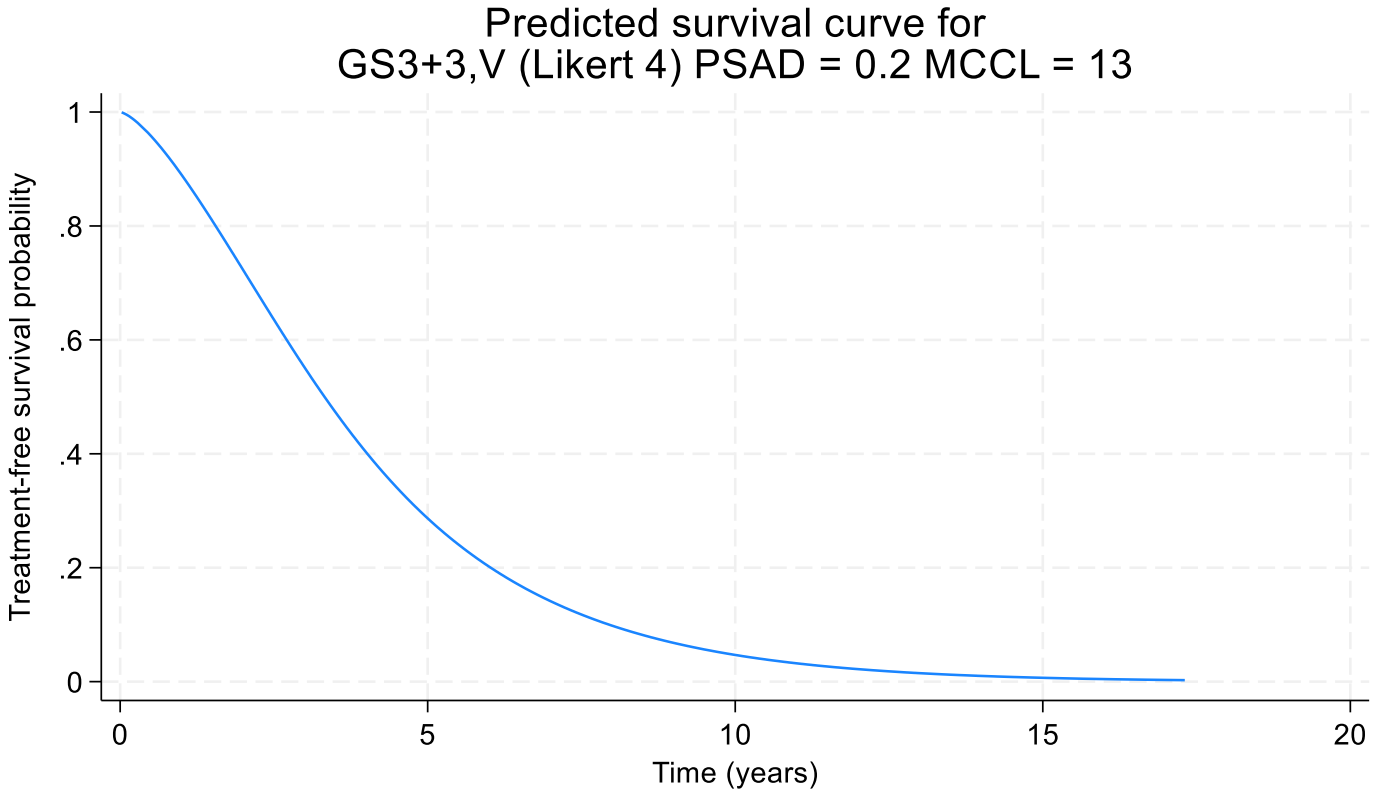


Treatment free survival

- 3 years 90%
- **5 years 75%**
- 10 years 50%

With particular thanks to Dr Busola Adebusoye

Mr Victor Intermediate risk
13mm Gleason 3 + 3
MRI visible (Likert 4)
PSA 12, 60 ml prostate PSAD 0.2

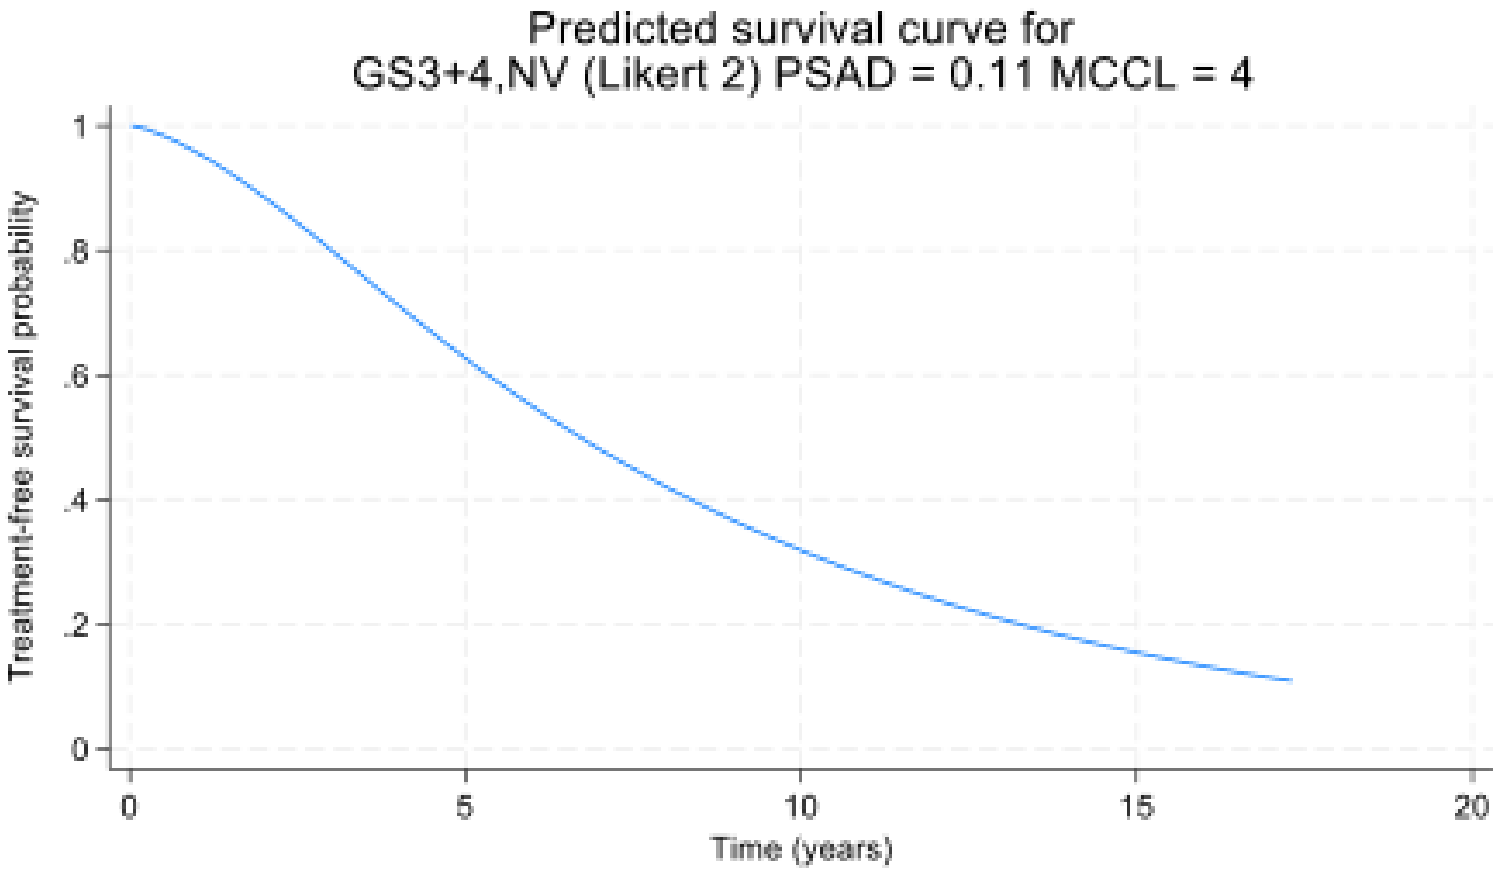


Treatment free survival

- 3 years 60%
- **5 years 25%**
- 10 years <10%

With particular thanks to Dr Busola Adebusoye

Mr Norman Another Intermediate risk
4mm Gleason 3 + 4
Not MRI visible (Likert 2)
PSA 5, prostate volume 45 mls, PSA density 0.11

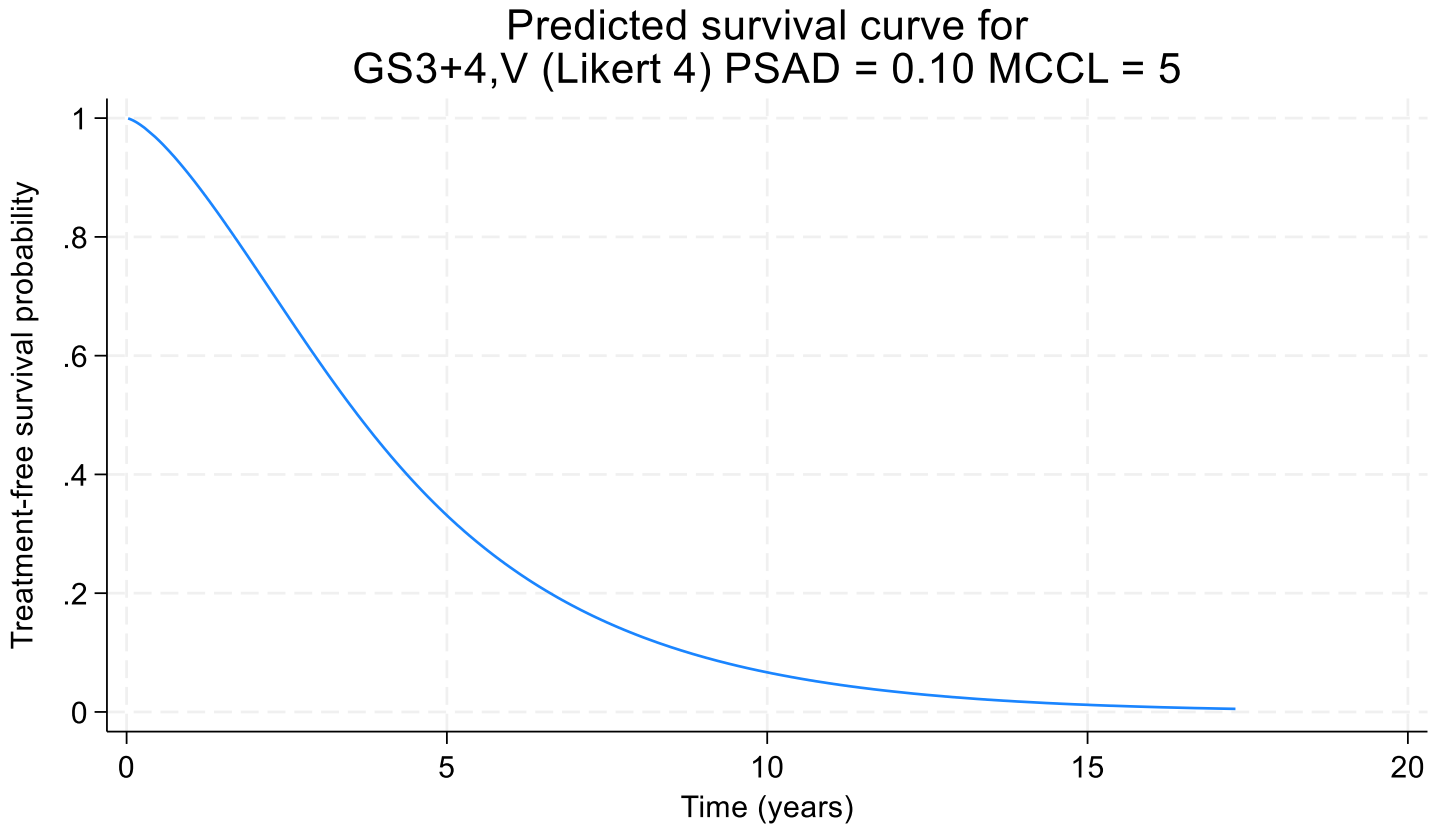


Treatment free survival

- 3 years 80%
- **5 years 60%**
- 10 years 33%

With particular thanks to Dr Busola Adebusoye

Mr Vince Increasing risk
5mm 3 + 4
MRI Visible (Likert 4)
PSA 5, 50 ml prostate PSAD 0.10



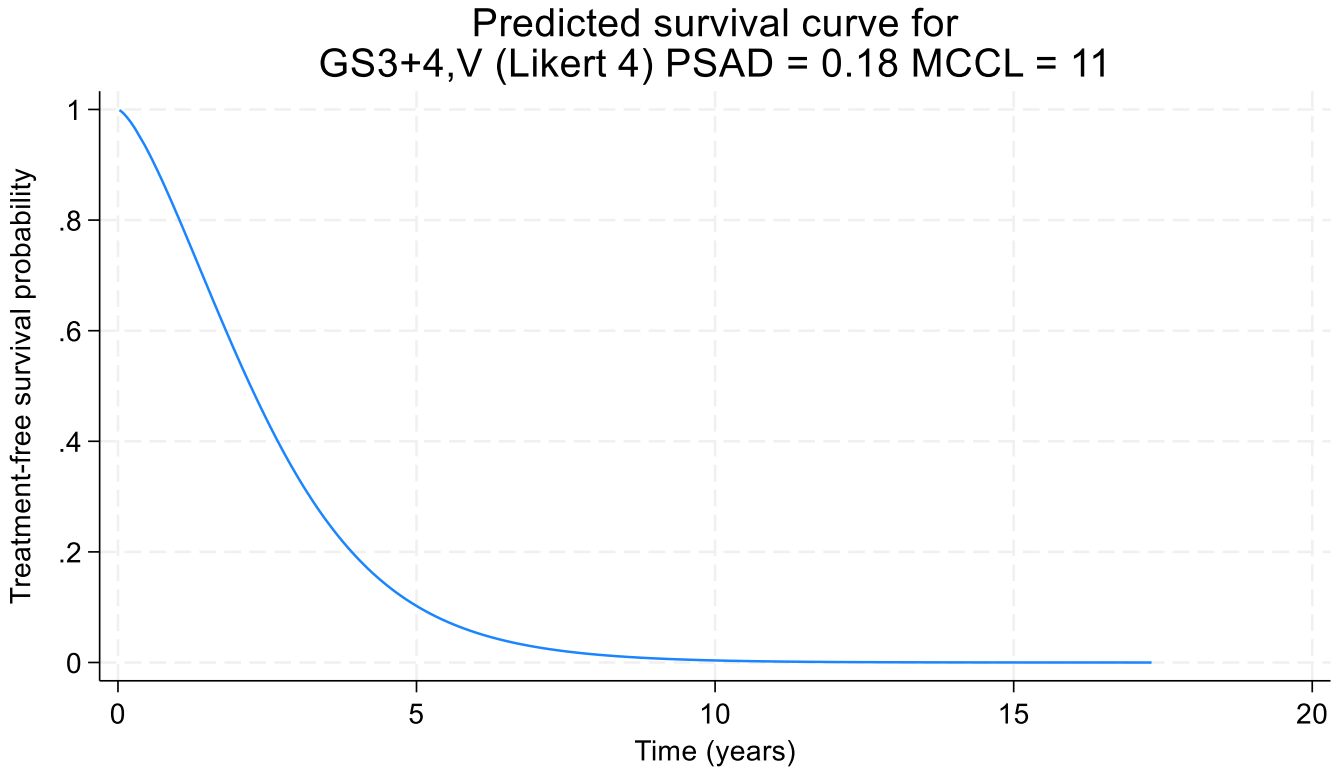
UCLH treatment free survival

- 3 years 60%
- **5 years 30%**
- 10 years 10%

With particular thanks to Dr Busola Adebusoye

Mr Harry Higher risk

11mm Gleason 3 + 4
MRI visible (Likert 4)
50 m l prostate PSA 9 PSAD 0.18



UCLH Treatment free survival

- 50% at 3 years
- **10% at 5 years**
- Negligible at 10

** Not recommended for AS

With particular thanks to Dr Busola Adebusoye

		Not visible on MRI (Likert 1-3)					Visible on MRI (Likert 4/5)

Summary

- Risk-adapted active surveillance makes sense
- When using an MRI-led pathway for diagnosis it makes sense to use an MRI-led, risk adapted pathway for monitoring
- Consider the risk factors to be:
  - Gleason score
  - MRI-visibility
  - Maximum cancer core length
  - PSA density (not PSA < or > 10 ng/ml)
- Always remember to assess the whole person not just the MRI!

Let’s move onto treatment…

Focal therapy for prostate cancer

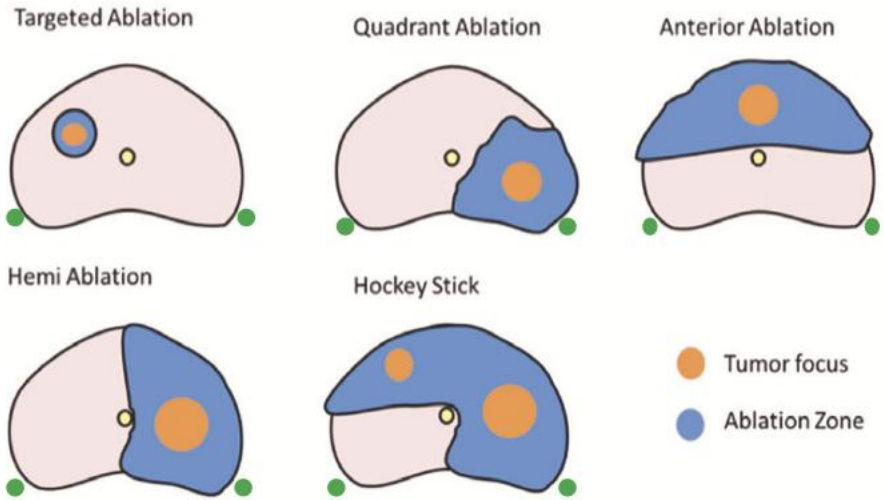
A small treatment for a small cancer

Risk of cancer progression

Risks of radical treatment

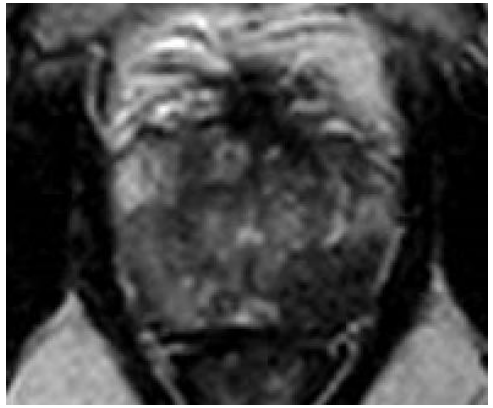
What do we mean by focal therapy?

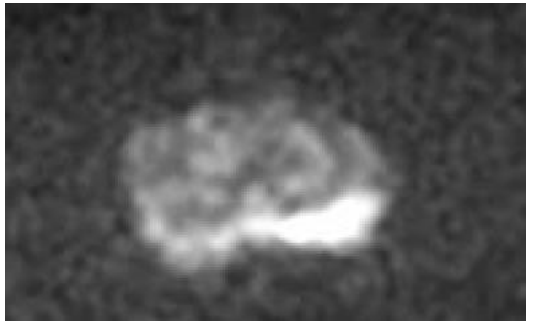
- Targeted to the index lesion
  - Gleason 3 + 4 or 4 + 3
  - Visible on MRI
  - With an adequate margin
- Using any modality
  - Heat
  - Ice
  - Electrical disruption
  - Others (laser, photodynamic therapy)

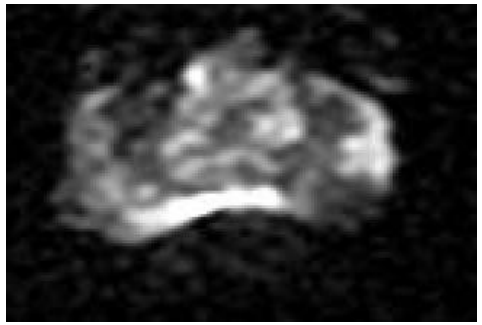


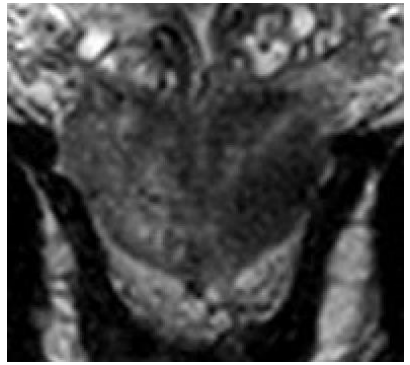
Typical case

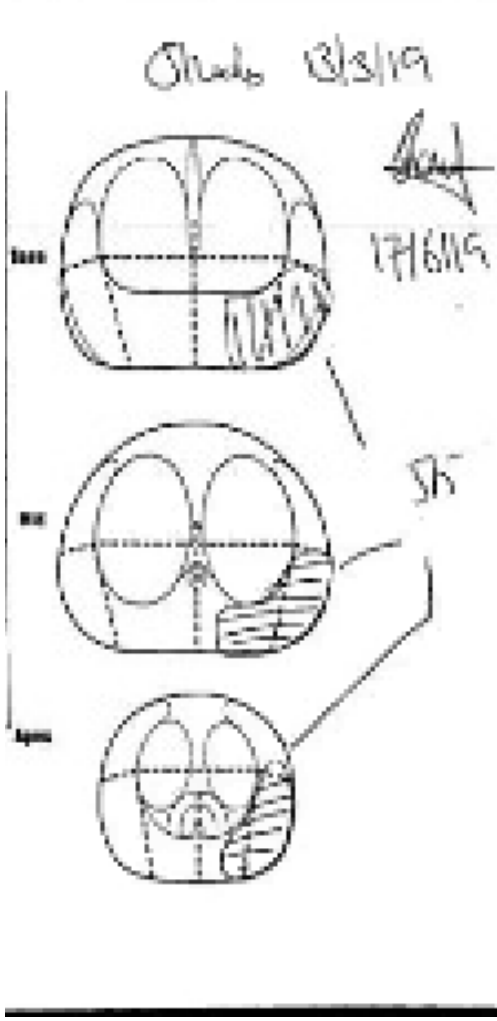
- MRI March 2019
- 12mm 3 + 4 on biopsy
- Left focal HIFU July 2019
- 4cm, 3cm, 3cm
- Excellent Uchida changes
- Day surgery procedure
- Catheter for 5 days

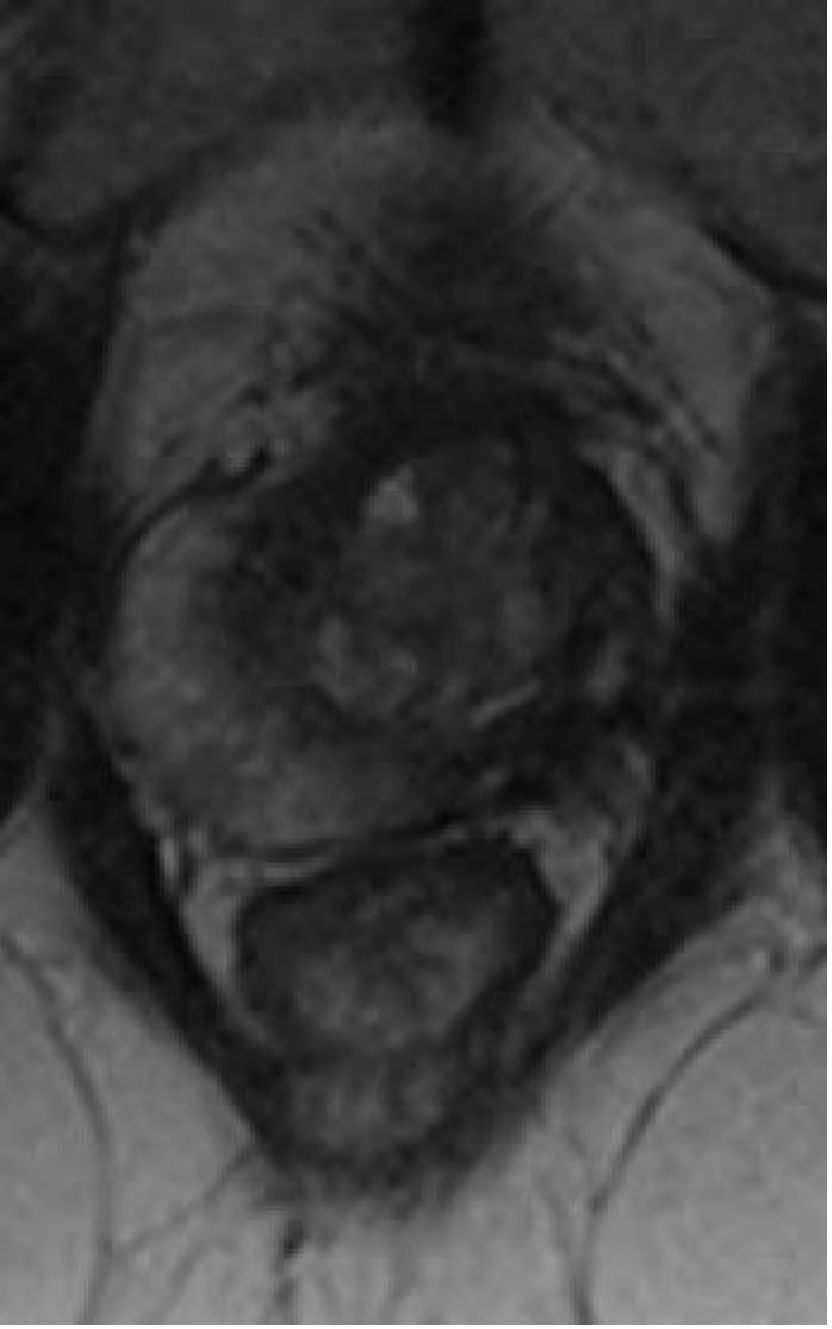






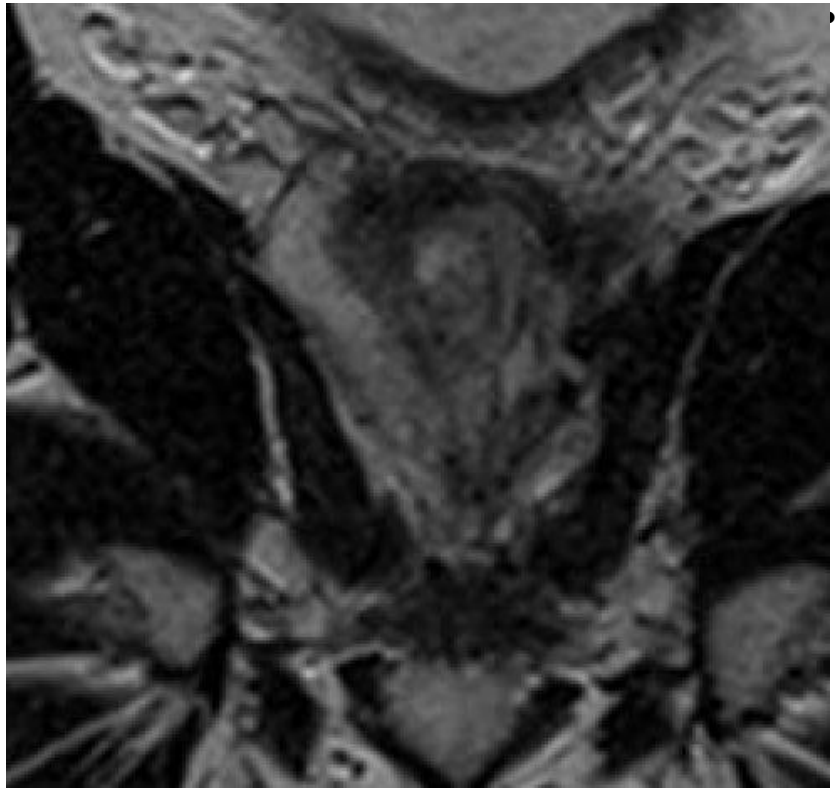


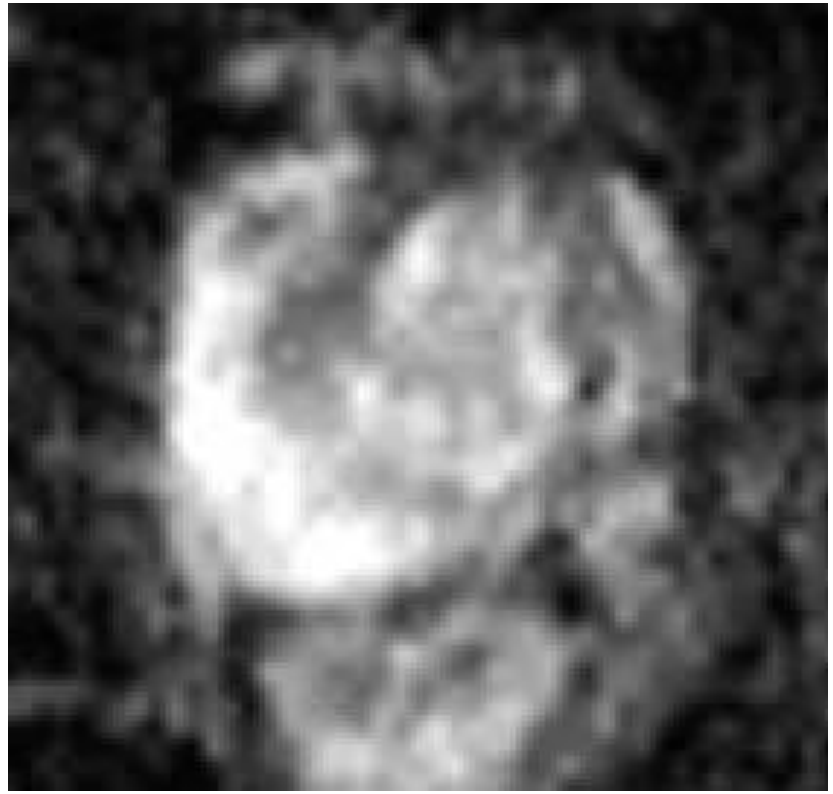




12 Month follow up

- PSA reduced from 6.9 to 1.9
- Good erections with no tablets
- No urinary symptoms
- Non-suspicious MRI





5 year follow up

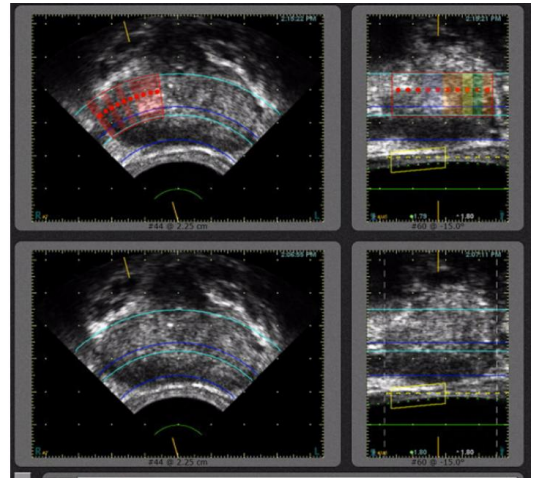
- PSA risen to 2.4
- Non-suspicious MRI

NCITA National Cancer Imaging Translational Accelerator

High Intensity focussed ultrasound (HIFU)

- **Most widely used energy source for focal therapy of localized prostate cancer.**
- **Ideal application:** treatment of posterolaterally located lesions, due to favorable accessibility and energy delivery profile.
- **Limitations:** less effective and technically challenging for apical lesions, where treatment precision is constrained by anatomical proximity to the sphincter and urethra.

- **Transrectal Systems:**
  - Sonablate® (SonaCare Medical, USA)
  - Focal One® (EDAP TMS, France)
- **Transurethral Systems:**
  - TULSA-PRO® (Profound Medical, Canada)
- **Emerging:**
  - MRI-guided transrectal HIFU (Insightec ExAblate®)

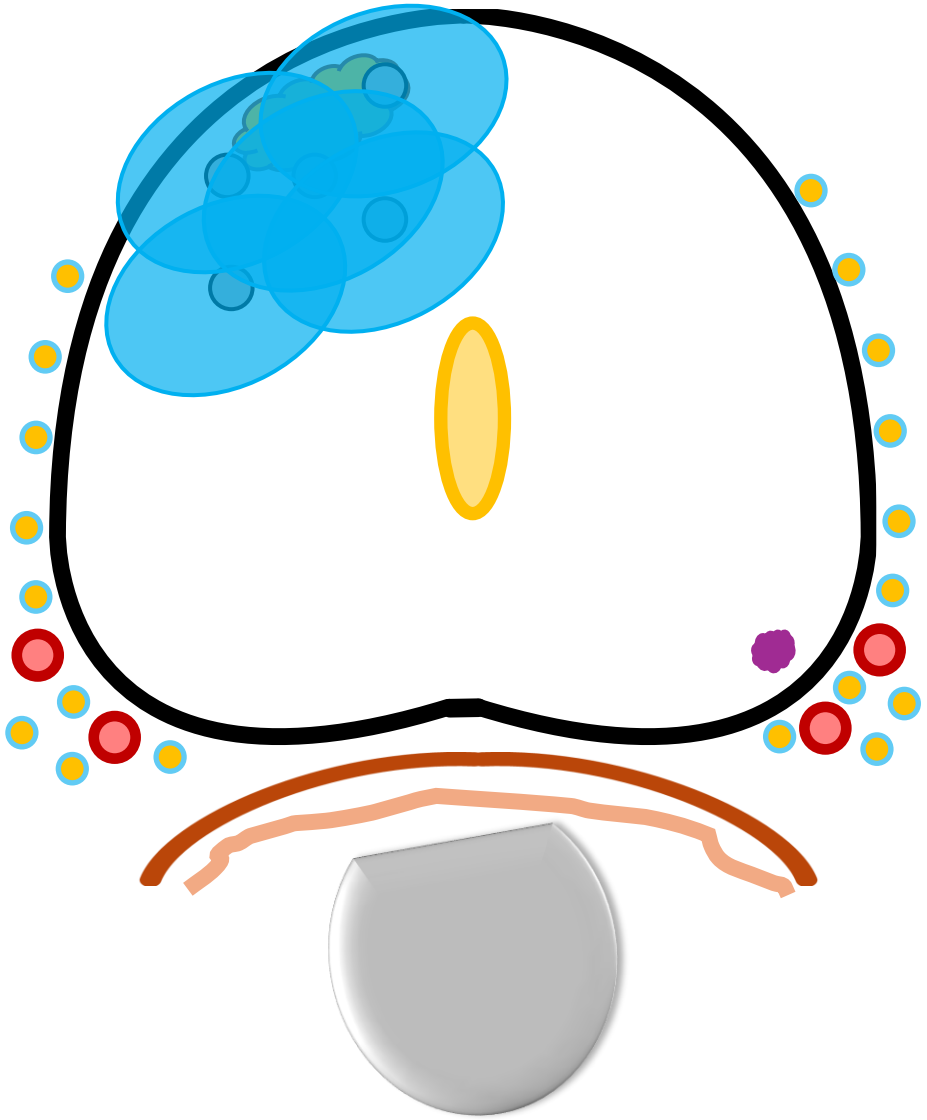


With thanks to Professor Rafael Sanchez-Salas

Cryotherapy

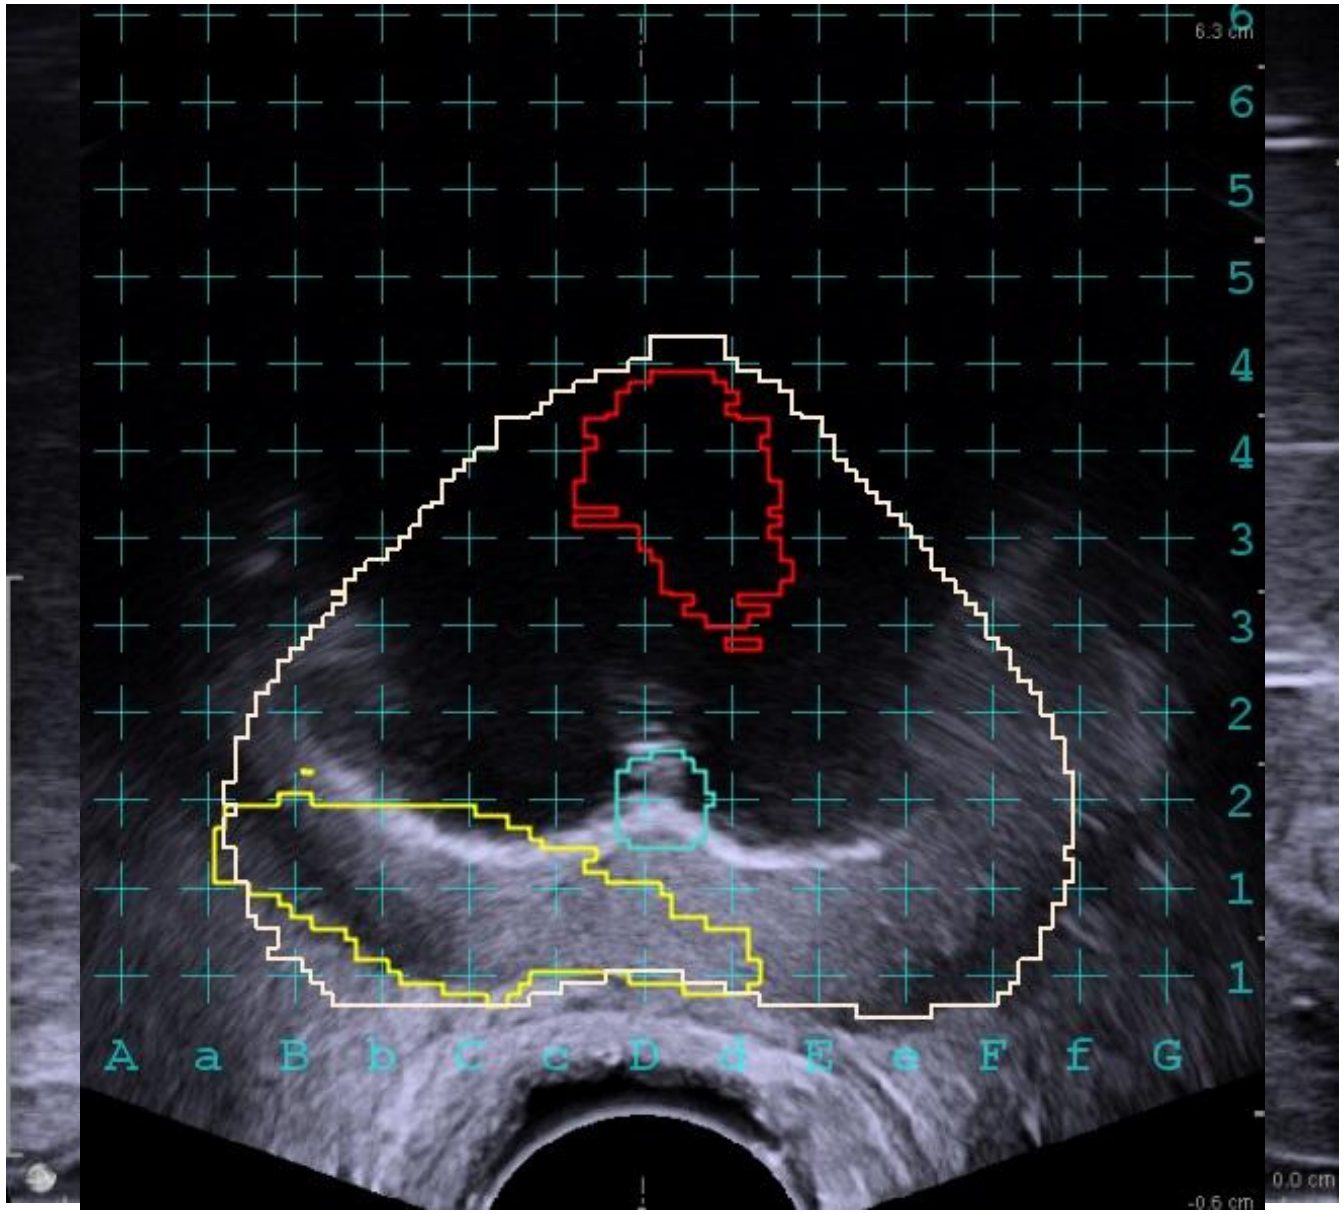
Medium and some high risk prostate cancers

- Cryotherapy
- Ultrasound probe in rectum to guide treatment
- Needles inserted through skin behind scrotum (perineal)
- Each needle grows an iceball down to temperatures of at least -40℃
- Can be repeated



With thanks to Professor Hashim Ahmed, Imperial College London

Cryotherapy



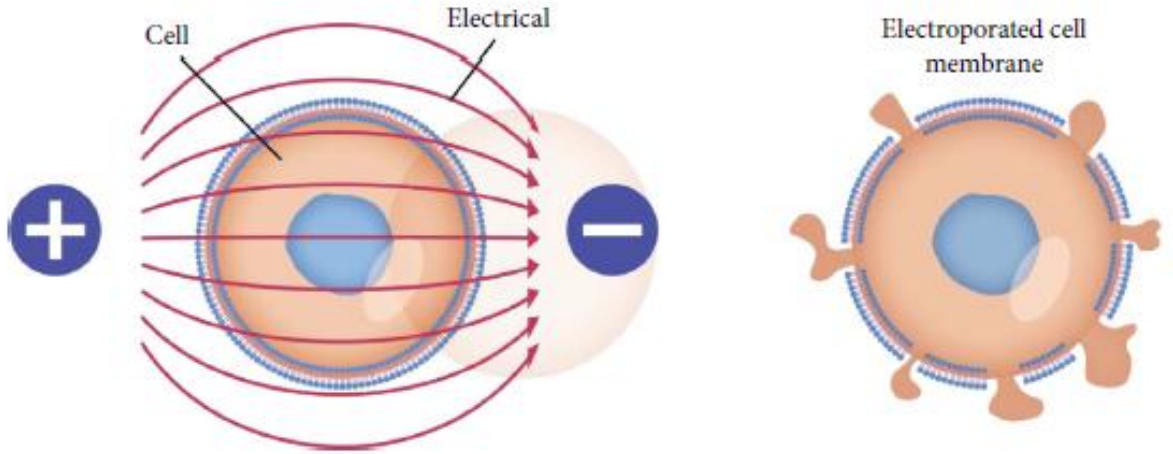
With thanks to Professor Hashim Ahmed, Imperial College London

Irreversible electroporation (IRE)

IRE is an ablative treatment for prostate cancer

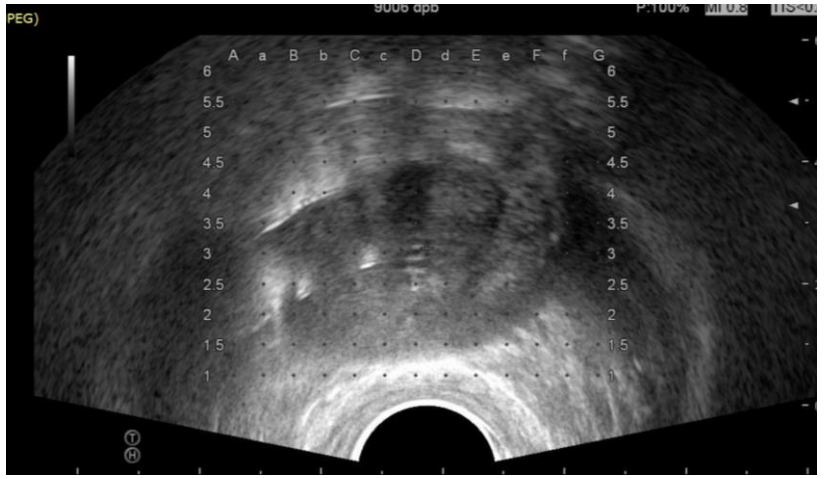
- Direct current is applied to the target area – electrodes (needles) via brachy grid
- Cell membranes are depolarised
- Excessive permeability leads to cell death by apoptosis
- HIFU and Cryo rely instead upon thermal injury and necrosis

Fig. 2 IRE is based on the principle of electroporation.



IRE

- Functional and oncological outcomes similar to HIFU/Cryo
- Short procedures (<60 mins)
- Short learning curve
  - Fusion if required
  - Energy delivery less dependent on USS skill
  - Non thermal ablation may offer advantage
- Harder at extreme apex, pacemakers
- ARC registry for prospective data collection



Medium-term oncological outcomes in a large cohort of men treated with either focal or hemi-ablation using high-intensity focused ultrasonography for primary localized prostate cancer

Radical treatment free survival 73% at 7 years

Overall failure free survival 69% at 7 years

Failure defined as

- evidence of cancer requiring whole-gland salvage treatment/ 3rd focal therapy
- systemic treatment
- prostate cancer metastases
- prostate cancer–specific death

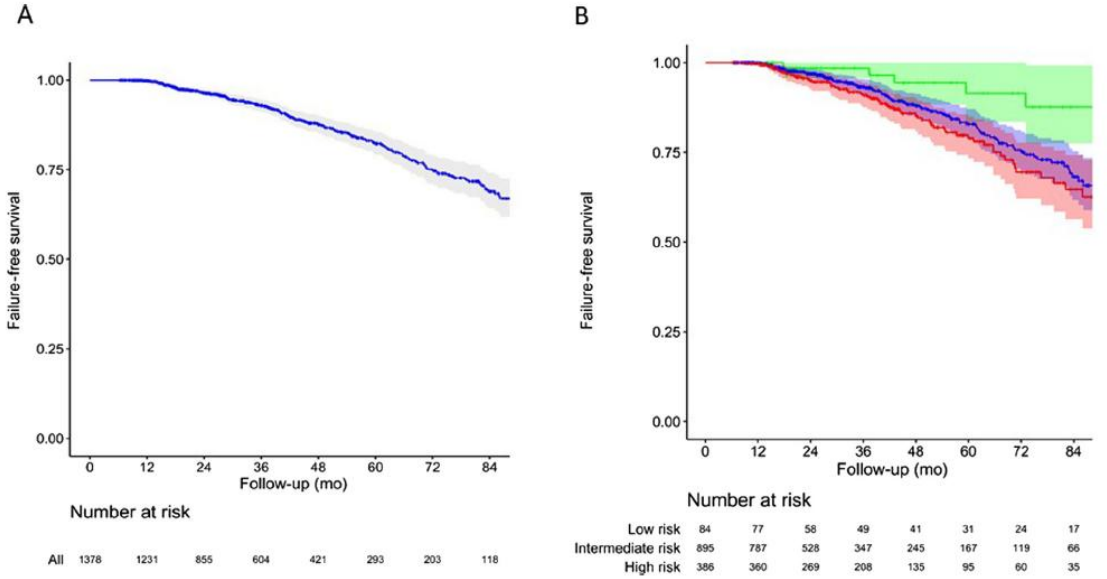

Fig. 1 – Kaplan-Meier curves of failure-free survival (FFS) with 95% confidence intervals. FFS is defined as transition to whole-gland salvage treatment or third focal therapy treatment, systematic treatment, and/or development of prostate cancer metastases and/or prostate cancer–specific death for (A) all patients with at least 6 mo of follow-up and (B) 1365 patients stratified per D'Amico low-risk (green line), intermediate-risk (blue line), and high-risk (red line) group (log-rank analysis of D'Amico intermediate- vs high-risk disease $p = 0.3$).

Received: 26 August 2020 / Revised: 29 November 2020 / Accepted: 11 December 2020

- Failure defined as need for local salvage treatment (RP or RT) or systemic treatment or development of metastatic disease
  - Biochemical recurrence after RP was not included (24.3% after matching, with 15.9% having salvage RT)
  - Prescence of positive biopsy after FT not included (23.9% after matching
    - 6.5% had radical after focal
    - 17.1% had 2nd focal (And <3% then had radical treatment)
    - 1.6% had 3 focal treatments)
- One additional focal treatment was allowed

Prostate Cancer and Prostatic Diseases
https://doi.org/10.1038/s41391-020-00315-y

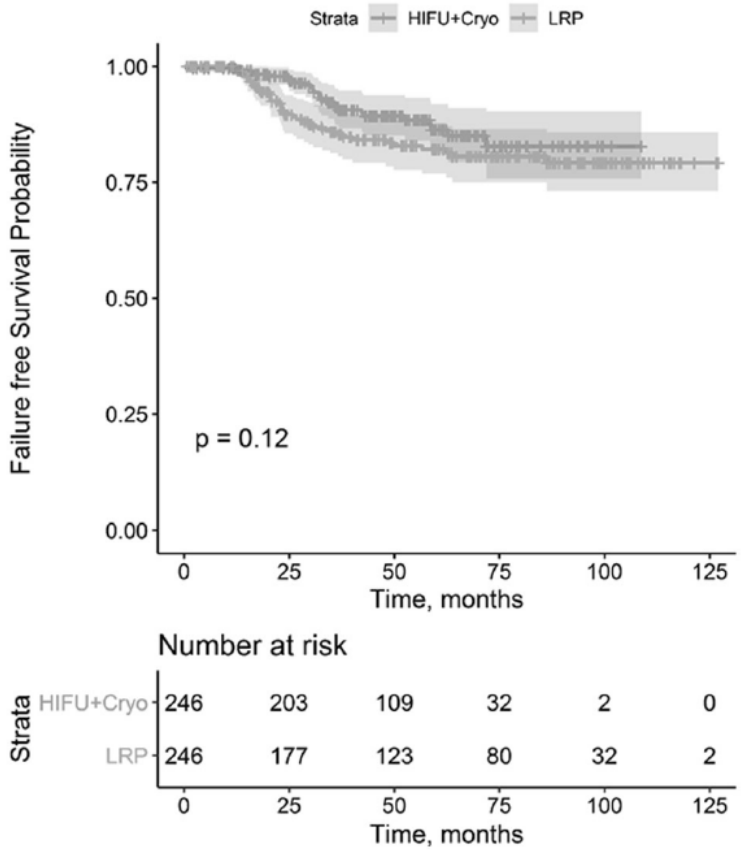

Fig. 2 Primary outcome (definition 1): Kaplan–Meier curve reporting failure free survival against time for laparoscopic radical prostatectomy and focal therapy, after 1–1 matching and single imputation. Failure-free survival (95% CI) in the radical prostatectomy (LRP) compared to focal therapy (HIFU + Cryo) groups was 86% (81–91%) vs. 91% (87–95%) at 3 years, 82% (77–88%) vs. 86% (81–92%) at 5 years and 79% (73–86%) vs 83% (76–90%) at 5 years, respectively (adjusted log rank *p* value 0.12).

3 year failure free survival

- 86% RP
- 91% FT

5 year failure free survival

- 82% RP
- 86% FT

8 year failure free survival

- 79% RP
- 83% FT

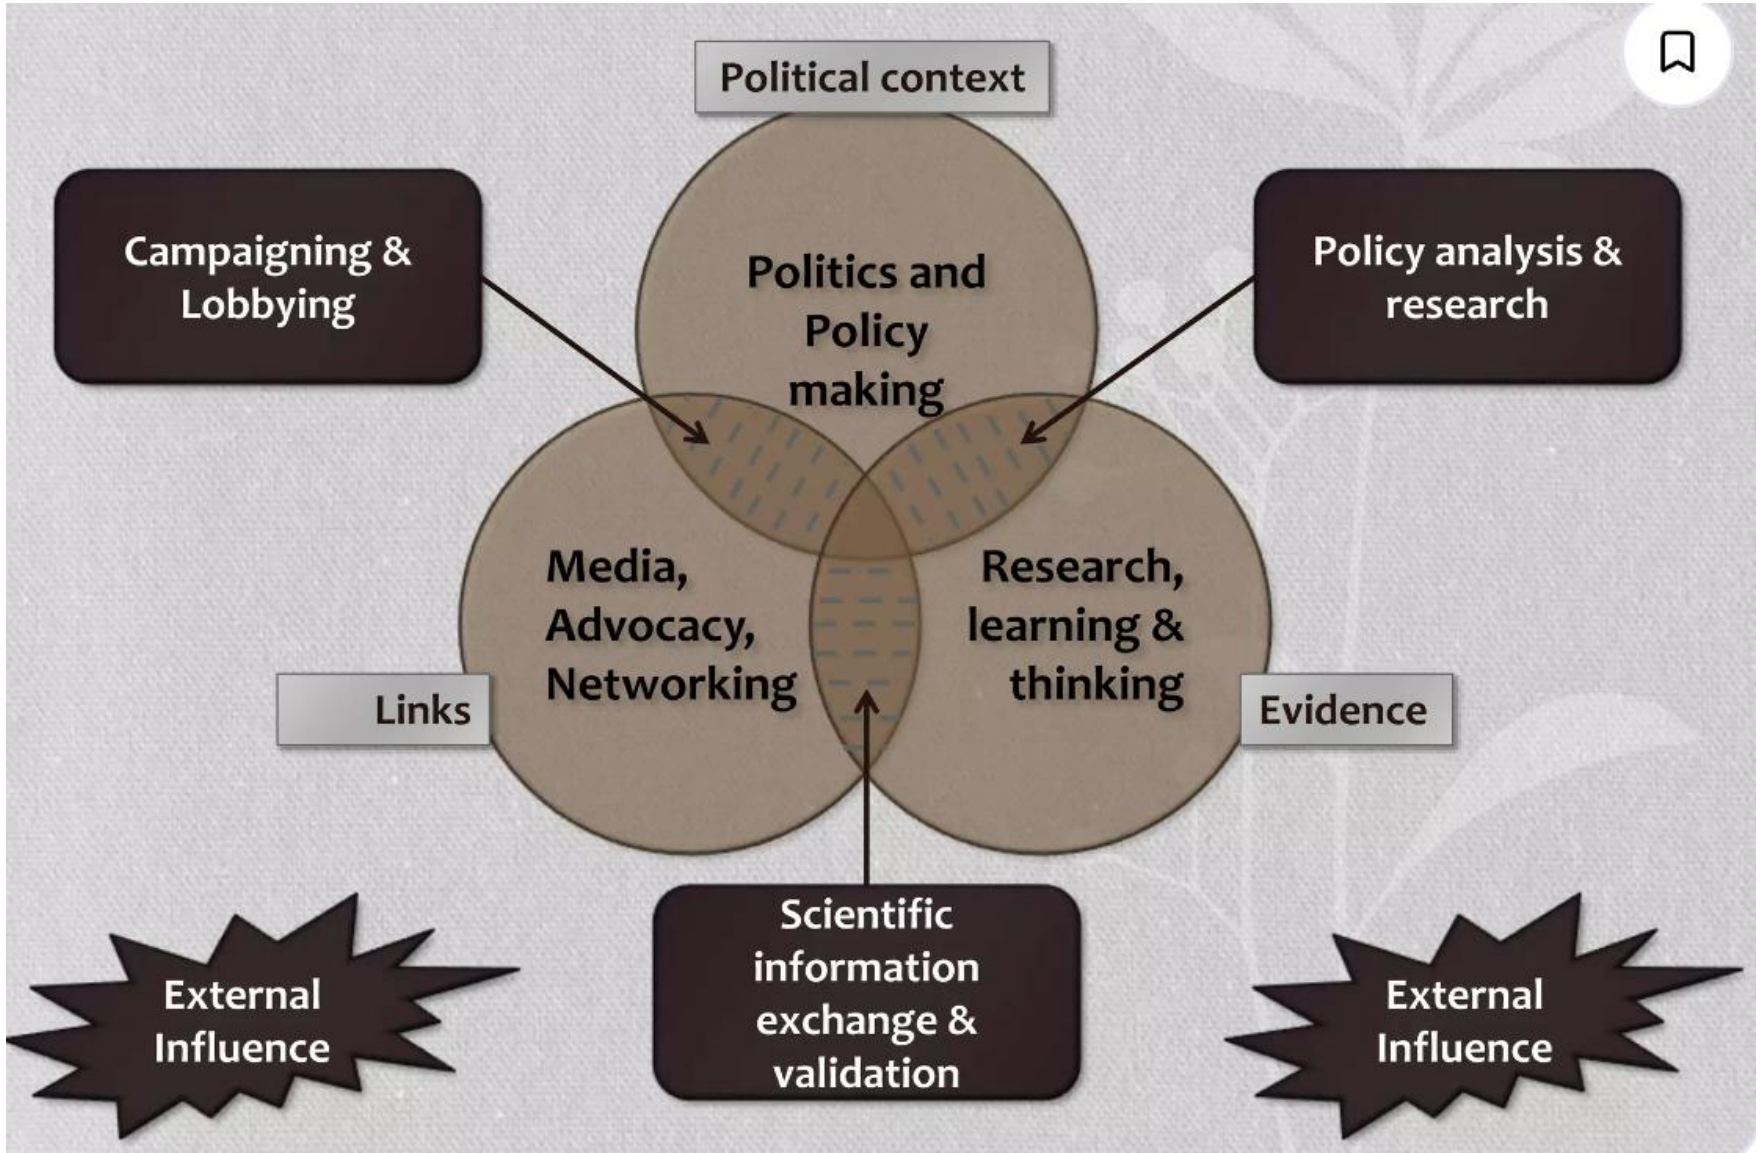
Change is not just about data and evidence



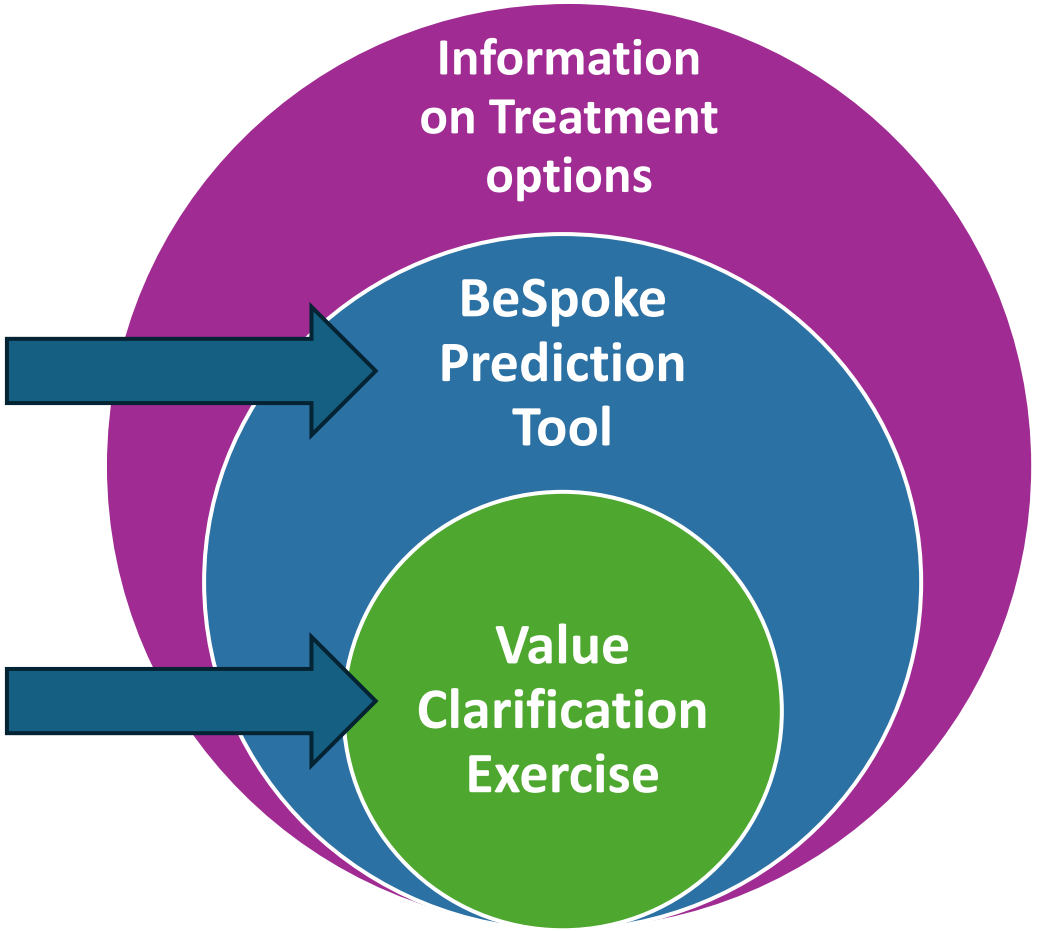
Focal therapy – has it reached prime time?

- The functional outcomes of focal therapy are well described and understood 
- The medium term (5-10 year outcomes) of focal therapy are well described and understood 
- Patients with unilateral clinically significant disease are offered focal therapy 
- Every eligible patient can choose focal therapy 
- Decisions re active treatment and treatment type are made based on cancer risk and personal choice 

NCITA
National Cancer Imaging Translational Accelerator

How does a patient with localized prostate cancer decide between very different choices?

BeSpoke Decision Support Tool



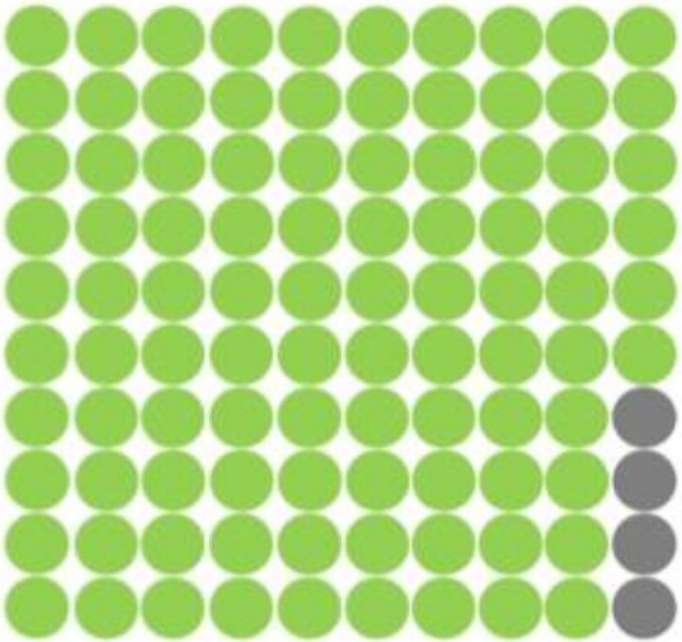
Personalised decision support based on UK data

- National Prostate Cancer audit for survival and retreatment
- TrueNTH UK Post surgery for functional outcomes
- UCLH active surveillance for MRI-led active surveillance outcomes

How likely am I to die from prostate cancer in the next 5 years?

Your clinical parameters:

- Age: 65 years
- PSA: 8 ng/mL
- Gleason Score: 3+4
- T Stage: T2



Legend:

- **Alive**
- **Death (from prostate cancer)**
- **Death (from other causes)**

Based on the information you have entered, **96 out of 100 men are alive** at 5 years after diagnosis.

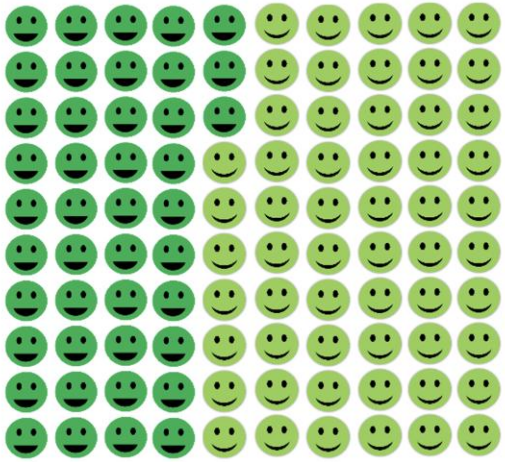
Of the men who would not survive, **four would die due to causes not related to prostate cancer.**

10 times more likely to die of other causes than prostate cancer in 15 years

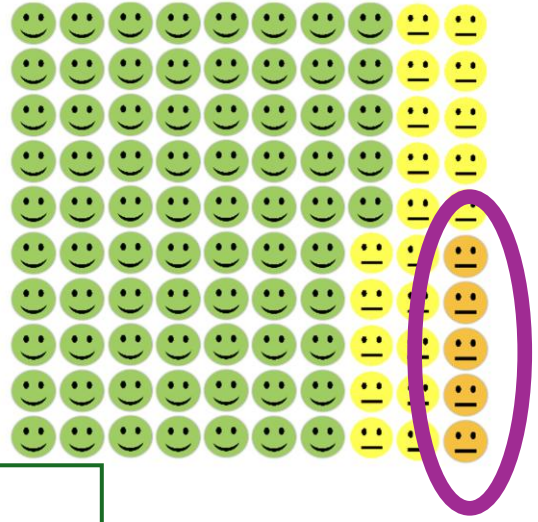
Will I need further treatment in the next 5 years?

1 in 20 men having focal treatment need radical treatment
1 in 14 men having surgery or radiotherapy need salvage treatment

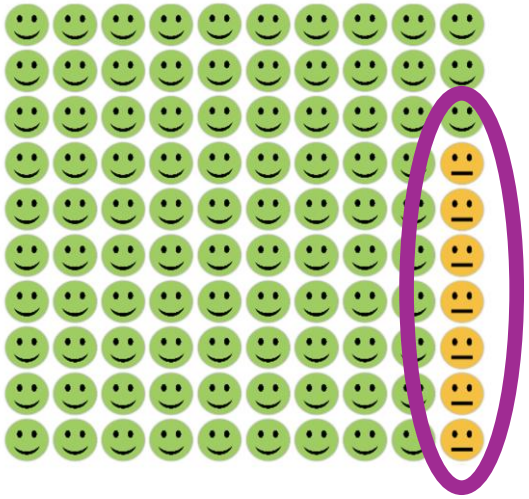
Active Surveillance



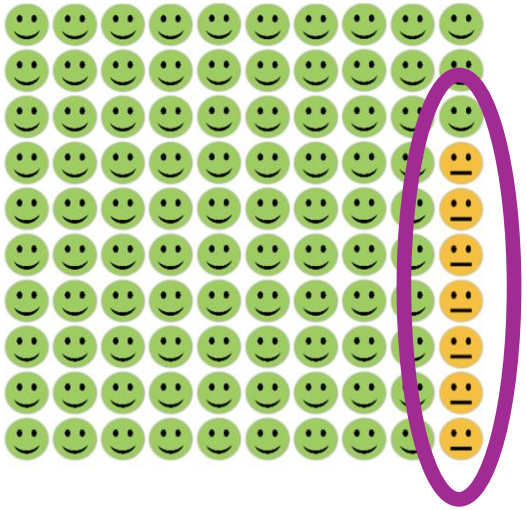
Focal Therapy



Prostatectomy



Radiotherapy



Your clinical parameters:

- Age: 65 years
- PSA: 8 ng/mL
- Prostate volume: 60 mL
- Gleason Score: 3+4
- T Stage: T2
- MRI visibility: Visible (Score 4-5)
- Maximal Cancer Core Length: 8mm

Legend:

- **No treatment (i.e. Active surveillance only)**
- **First treatment only (i.e. focal therapy, Prostatectomy, Radiotherapy)**
- **Second Focal treatment**
- **Progressed to different treatment (i.e. Radiotherapy or surgery after focal therapy; Salvage radiotherapy after surgery; Hormone treatment after radiotherapy)**

How likely am I to leak urine at 1 year after treatment?

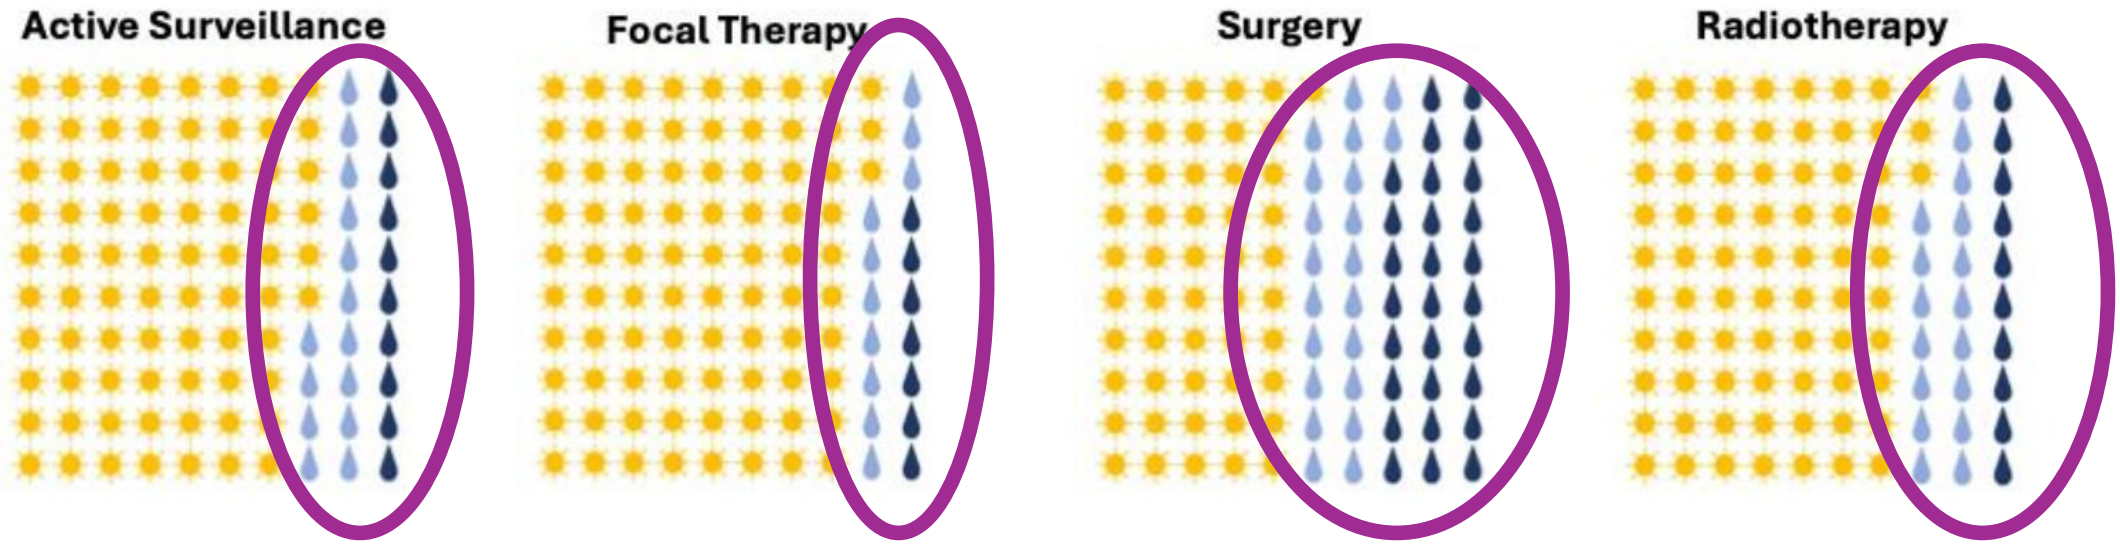
Leaking urine is a common side effect after most prostate cancer treatments. Each treatment carries a different risk. For 100 men with similar urinary function as you (see box), the following icon chart represents the risk of leaking urine at 1 year from receiving each of the following treatments.

Your current degree of urine leakage:

Rarely or never leaking

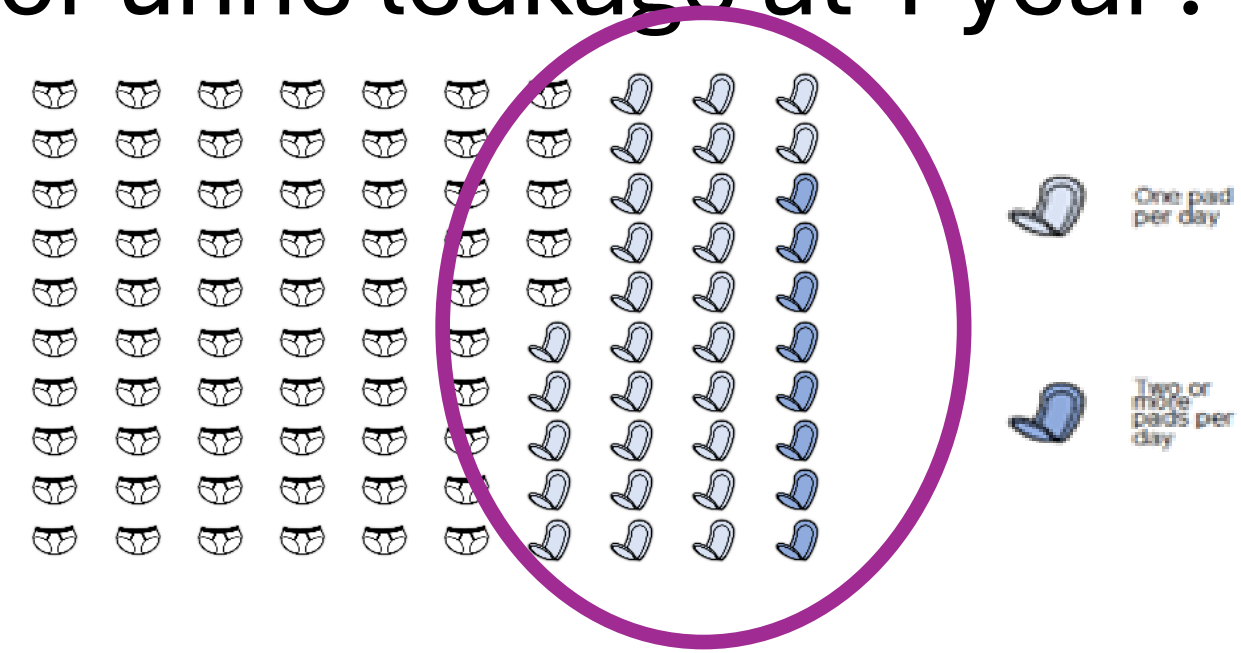
Urinary Leakage - Legend

- **Rarely or never leaking**
- **Leaking once a week or more**
- **Leaking once a day or more**



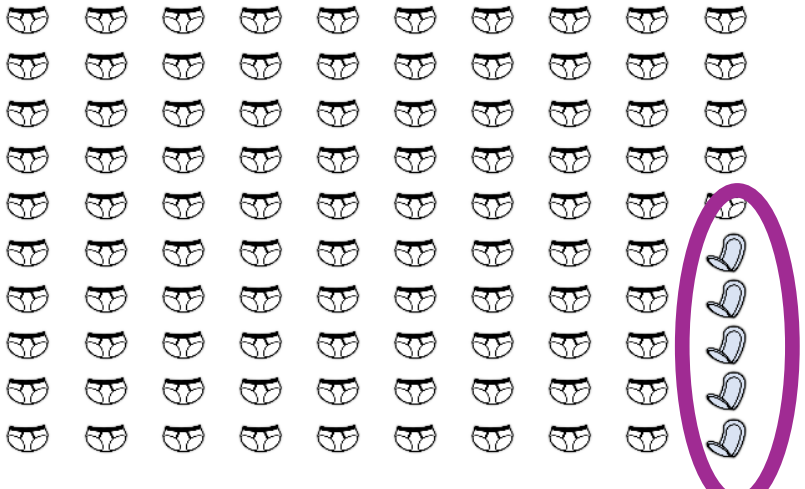
Will I need pads for urine leakage at 1 year?

Active Surveillance

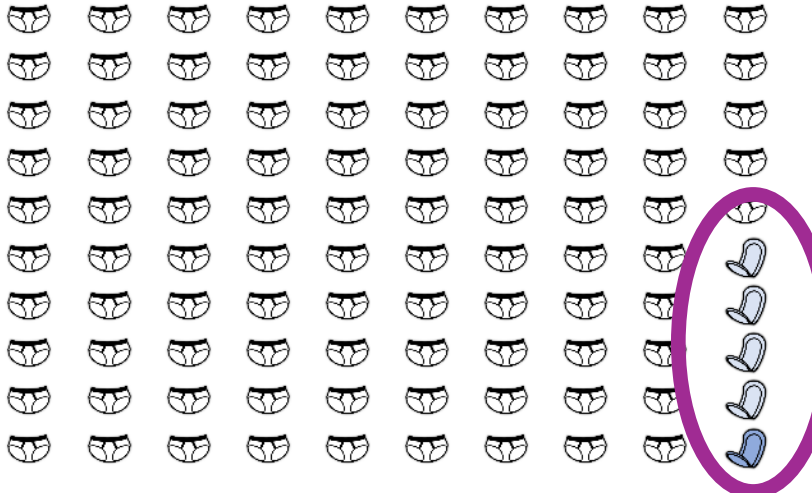


Surgery

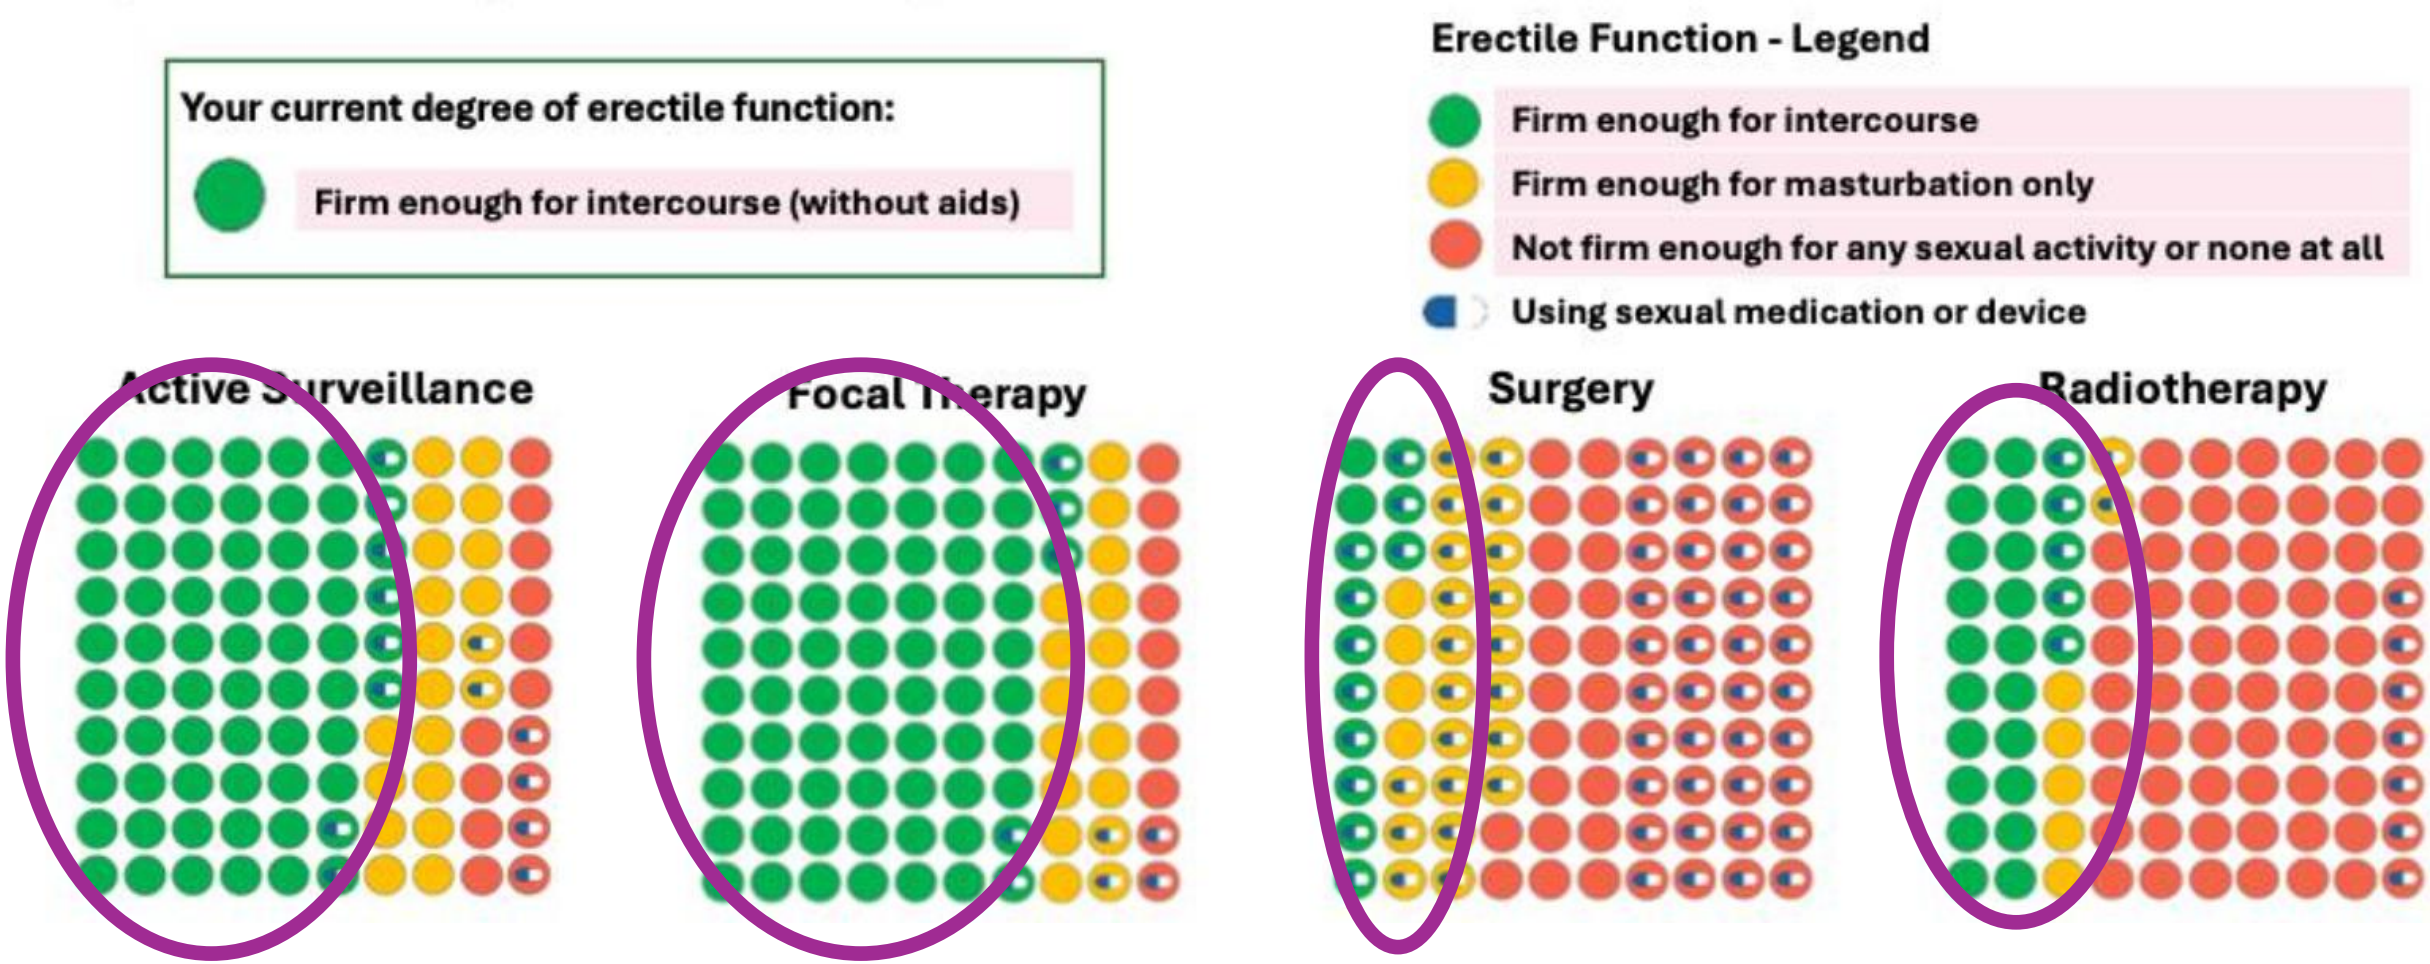
Focal treatment



Radiotherapy



How will my erections be at 12 months after treatment?

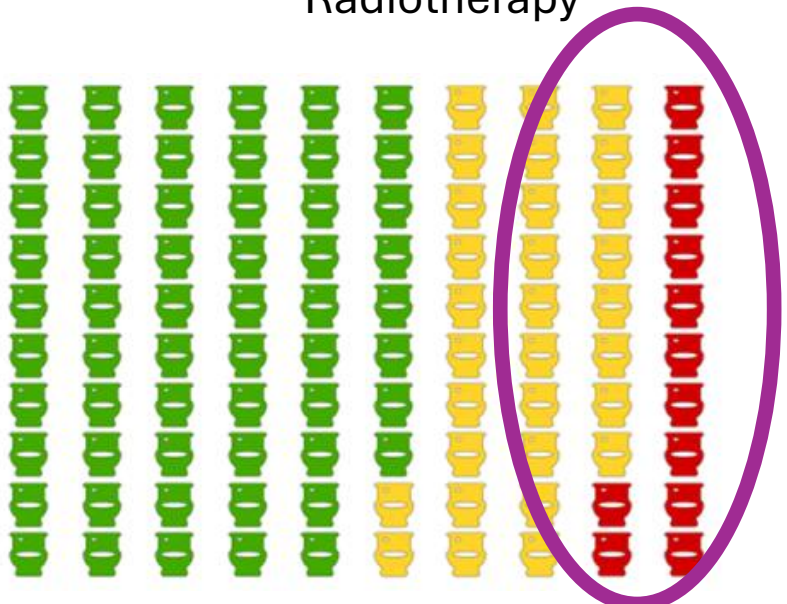


How will my bowel function be at 12 months after treatment?

Active Surveillance

Surgery

Radiotherapy



Focal treatment

PSA after radical treatment for prostate cancer

- NPCA data
  - Around 1 in 3 men with a new diagnosis have radiotherapy
  - Around 1 in 6 men with a new diagnosis have surgery to remove the prostate
- PSA is an excellent tool for follow up when the whole prostate has been treated
  - Simple
  - Any detectable PSA needs monitoring

PSA in practice summary

- The first available test for prostate cancer
- PSA based screening leads to a reduction in prostate cancer death
- TRANSFORM will look at new ways to screen
  - MRI
  - Polygenic risk score
- In MRI-led active surveillance PSA density is more helpful than PSA
- PSA is useful in follow up, particularly after radical treatment

Any questions?
